## Definitions, Acronyms, and Abbreviations

**Table 2: Definitions, Acronyms, and Abbreviations**

<table>
<thead>
<tr>
<th>Term</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>SR-IOV</td>
<td>Single Root I/O Virtualization (SR-IOV) is a specification that allows a PCI device to appear virtually on multiple Virtual Machines (VMs), each of which has its own virtual function. This specification defines virtual functions (VFs) for the VMs and a physical function for the hypervisor. Using SR-IOV in a cloud infrastructure helps to achieve higher performance since traffic bypasses the TCP/IP stack in the kernel.</td>
</tr>
<tr>
<td>RoCE</td>
<td>RDMA over Converged Ethernet (RoCE) is a standard protocol which enables RDMA’s efficient data transfer over Ethernet networks allowing transport offload with hardware RDMA engine implementation, and superior performance. RoCE is a standard protocol defined in the InfiniBand Trade Association (IBTA) standard. RoCE makes use of UDP encapsulation allowing it to transcend Layer 3 networks. RDMA is a key capability natively used by the InfiniBand interconnect technology. Both InfiniBand and Ethernet RoCE share a common user API but have different physical and link layers.</td>
</tr>
<tr>
<td>ConnectX®-5</td>
<td>ConnectX-5 adapter cards support two ports of 100Gb/s Ethernet connectivity, sub-700 nanosecond latency, a very high message rate, and PCIe switch and NVMe over Fabric offloads, providing the highest performance and most flexible solution for the most demanding applications and markets. It uses Accelerated Switching and Packet Processing (ASAP²™) technology which enhances offloading of virtual switches and virtual routers, such as Open V-Switch (OVS), which results in significantly higher data transfer performance without overloading the CPU. Together with native RoCE and DPDK (Data Plane Development Kit) support, ConnectX-5 dramatically improves Cloud and NFV platform efficiency.</td>
</tr>
<tr>
<td>Open vSwitch (OVS)</td>
<td>Open vSwitch (OVS) allows Virtual Machines (VM) to communicate with each other and with the outside world. OVS traditionally resides in the hypervisor and switching is based on twelve tuples matching on flows. The OVS software-based solution is CPU intensive, affecting system performance and preventing fully utilizing available bandwidth.</td>
</tr>
<tr>
<td>OVS-DPDK</td>
<td>OVS-DPDK extends Open vSwitch performances while interconnecting with Mellanox DPDK Poll Mode Driver (PMD). It accelerates the hypervisor networking layer for better latency and higher packet rate while maintaining Open vSwitch data plane networking characteristics.</td>
</tr>
<tr>
<td>ASAP²</td>
<td>Mellanox ASAP²—Accelerated Switching And Packet Processing® technology allows to offload OVS by handling OVS data-plane in Mellanox ConnectX-5 (and onwards) NIC hardware (Mellanox Embedded Switch or eSwitch) while maintaining OVS control-plane unmodified. As a result, we observe significantly higher OVS performance without the associated CPU load. The current actions supported by ASAP² include packet parsing and matching, forward, drop along with VLAN push/pop or VXLAN encapsulated/decapsulated.</td>
</tr>
<tr>
<td>Term</td>
<td>Description</td>
</tr>
<tr>
<td>---------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>NVMEoF</td>
<td>NVMeOF or NVMe over Fabrics is a network protocol, like iSCSI, used to communicate between a host and a storage system over a network (a.k.a. fabric). It depends on and requires the use of RDMA. NVMeOF can use any of the RDMA technologies including InfiniBand and RoCE.</td>
</tr>
</tbody>
</table>
1 Mellanox OVS Hardware Offloading Support for TripleO

TripleO (OpenStack On OpenStack) is a program aimed at installing, upgrading, and operating OpenStack clouds using OpenStack’s own cloud facilities as the foundations, building on Nova, Neutron, and Heat to automate fleet management at datacenter scale.

Open vSwitch (OVS) allows Virtual Machines (VMs) to communicate with each other and with the outside world. OVS traditionally resides in the hypervisor and the switching is based on twelve-tuple matching on flows. The OVS software-based solution is CPU intensive, affecting system performance and prevents the full utilization of the available bandwidth. ASAP²—Accelerated Switching and Packet Processing® technology allows to offload OVS by handling the OVS data plane in Mellanox ConnectX-5 Network Interface Card (NIC) hardware (embedded switch or eSwitch) while leaving the control-plane of the OVS unmodified. As a result, the OVS performance significantly increases without the associated CPU load.

This Application Notes document details how to enable the Mellanox ASAP² technology feature of hardware-offloading support over OVS and OVN mechanism drivers.

1.1 Supported Features

TripleO Stein supports the following features:

- ASAP² with OVS mechanism driver
- ASAP² with OVN mechanism driver
- OVS over DPDK with inbox driver
- NVMe over Fabric (NVMeOF)
- BlueField with bare metal
1.2 System Requirements

The system requirements are detailed in the following table.

Table 3: Undercloud Node Requirements

<table>
<thead>
<tr>
<th>Platform</th>
<th>Type and Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>OS</td>
<td>Red Hat Enterprise Linux 7.6.</td>
</tr>
<tr>
<td>CPU</td>
<td>8-core 64-bit x86 processor with support for the Intel 64 or AMD64 CPU extensions.</td>
</tr>
<tr>
<td>Memory</td>
<td>Minimum 16 GB of RAM.</td>
</tr>
<tr>
<td>Disk Space</td>
<td>Minimum 40 GB of available disk space on the root disk. At least 10 GB of free space should be left before attempting an overcloud deployment or update. This free space accommodates image conversion and caching during the node provisioning process.</td>
</tr>
<tr>
<td>Networking</td>
<td>Minimum of 2 x 1Gb/s NICs. However, it is recommended to use a 10Gb/s interface for provisioning network traffic, especially if provisioning many nodes in the overcloud environment. Use Mellanox NIC for tenant network.</td>
</tr>
</tbody>
</table>

1.3 Supported Network Interface Cards and Firmware

Mellanox support for TripleO Stein supports the following Mellanox NICs and their corresponding firmware versions:

<table>
<thead>
<tr>
<th>NIC</th>
<th>Supported Protocols</th>
<th>Recommended Firmware Rev.</th>
</tr>
</thead>
<tbody>
<tr>
<td>BlueField</td>
<td>Ethernet</td>
<td>18.25.1020</td>
</tr>
<tr>
<td>ConnectX®-5</td>
<td>Ethernet</td>
<td>16.25.1020</td>
</tr>
<tr>
<td>ConnectX®-4 Lx</td>
<td>Ethernet</td>
<td>14.25.1020</td>
</tr>
<tr>
<td>ConnectX®-4</td>
<td>Ethernet</td>
<td>12.25.1020</td>
</tr>
<tr>
<td>ConnectX®-3 Pro</td>
<td>Ethernet</td>
<td>2.42.5000</td>
</tr>
</tbody>
</table>

1.4 Supported Operating Systems

The following operating systems are the supported:

Table 4: Supported Operating Systems

<table>
<thead>
<tr>
<th>OS</th>
<th>Platform</th>
</tr>
</thead>
<tbody>
<tr>
<td>RHEL7.6</td>
<td>x86_64</td>
</tr>
</tbody>
</table>
1.5 Overcloud Operating System Versions

The following overcloud operating system versions are supported:

*Table 5: Overcloud Operating System Versions*

<table>
<thead>
<tr>
<th>Item</th>
<th>Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>Kernel</td>
<td>kernel-5.0.0-1.x86_64</td>
</tr>
<tr>
<td></td>
<td>kernel-headers-5.0.0-1.x86_64</td>
</tr>
<tr>
<td>Iproute</td>
<td>openvswitch-2.11.1-1.el7.centos.x86_64</td>
</tr>
<tr>
<td>Open vSwitch</td>
<td>openvswitch-2.11.1-1.el7.centos.x86_64</td>
</tr>
</tbody>
</table>
2 ASAP² Support

2.1 ASAP² Support Over Open vSwitch

2.1.1 Network Card Support Matrix and Limitations

The following Mellanox cards support ASAP² hardware offloading feature:

<table>
<thead>
<tr>
<th>NICs</th>
<th>Supported Protocols</th>
</tr>
</thead>
<tbody>
<tr>
<td>ConnectX®-5</td>
<td>Ethernet</td>
</tr>
</tbody>
</table>

2.1.2 Configuration

Starting from a fresh RHEL 7.6 bare metal server, install and configure the undercloud according to the official TripleO installation documentation.

1. Use the ovs-hw-offload.yaml file from the following location:

```
/usr/share/openstack-tripleo-heat-templates/environments/ovs-hw-offload.yaml
```

Configure it over VLAN/VXLAN setup in the following way:

a. In the case of a VLAN setup, configure the ovs-hw-offload.yaml:

```
# A Heat environment file that enables OVS Hardware Offload in the overcloud.
# This works by configuring SR-IOV NIC with switchdev and OVS Hardware Offload on
# compute nodes. The feature supported in OVS 2.8.0

parameter_defaults:
  NeutronFlatNetworks: datacentre
  NeutronNetworkType:
    - vlan
  NeutronTunnelTypes: ''

NovaSchedulerDefaultFilters:

NovaSchedulerAvailableFilters:
["nova.scheduler.filters.all_filters","nova.scheduler.filters.pci_passthrough_filter.PciPassthroughFilter"]

ComputeSriovParameters:
  NeutronBridgeMappings:
    - datacentre:br-ex
  OvsHwOffload: True
```
b. In the case of a VXLAN setup, do the following:

i. Configure the `ovs-hw-offload.yaml`:

```yaml
# A Heat environment file that enables OVS Hardware Offload in the overcloud.
# This works by configuring SR-IOV NIC with switchdev and OVS Hardware Offload on
# compute nodes. The feature supported in OVS 2.8.0

parameter_defaults:
  NeutronFlatNetworks: datacentre

NovaSchedulerDefaultFilters:

NovaSchedulerAvailableFilters:
  ['nova.scheduling.filters.all_filters', 'nova.scheduling.filters.pci_passthrough_filter.PciPassthroughFilter']

NovaPCIPassthrough:
  - devname: <interface_name>
    physical_network: null
    # Mapping of SR-IOV PF interface to neutron physical_network.
    # In case of Vxlan/GRE physical_network should be null.
    # In case of flat/vlan the physical_network should as configured in
    # neutron.

  ComputeSriovParameters:
  NeutronBridgeMappings:
  - datacentre: br-ex
  OvsHwOffload: True
```

ii. Configure the interface names in the `/usr/share/openstack-tripleo-heat-templates/network/config/single-nic-vlans/control.yaml` files by adding the following code to move the tenant network from VLAN on a bridge to be on a separated interface.

```yaml
- type: interface
  name: <interface_name>
  addresses:
    - ip_netmask: get_param: TenantIpSubnet
```

iii. Configure the interface names in the `/usr/share/openstack-tripleo-heat-templates/network/config/single-nic-vlans/compute.yaml` files by adding the following code to move the tenant network from VLAN on a bridge to be on a separated interface.

```yaml
- type: sriov_pf
  name:
    get_param: enp3s0f0
  link_mode: switchdev
  numvfs: 64
  promisc: true
  use_dhcp: false
```

2. Create a new role for the compute node and change it to ComputeSriov.

```bash
# openstack overcloud roles generate -o roles_data.yaml Controller
ComputeSriov
```
3. Update the `~/cloud-names.yaml` accordingly. 
   See the following example:

   ```yaml
   parameter_defaults:
   ComputeSriovCount: 2
   OvercloudComputeSriovFlavor: compute
   ```

4. Assign the `compute.yaml` file to the `ComputeSriov` role. Update the `~/heat-templates/environments/net-single-nic-with-vlans.yaml` file by adding the following line:

   ```yaml
   OS::TripleO::ComputeSriov::Net::SoftwareConfig: ../network/config/single-nic-vlans/compute.yaml
   ```

5. Run `overcloud-prep-containers.sh`

2.1.3 Deploying the Overcloud

Deploy the overcloud using the appropriate templates and yamls from `~/heat-templates` as in the following example:

```bash
openstack overcloud deploy \
  --templates ~/heat-templates \
  --libvirt-type kvm -f ~/roles_data.yaml \
  -e /home/stack/containers-default-parameters.yaml \
  -e ~/heat-templates/environments/docker.yaml \
  -e ~/heat-templates/environments/ovs-hw-offload.yaml \
  --control-flavor oooq_control \
  --compute-flavor oooq_compute \
  --ceph-storage-flavor oooq_ceph \
  --block-storage-flavor oooq_blockstorage \
  --swift-storage-flavor oooq_objectstorage \
  --timeout 90 \
  -e ~/home/stack/containers-default-parameters.yaml \
  -e ~/heat-templates/environments/network-isolation.yaml \
  -e ~/heat-templates/environments/net-single-nic-with-vlans.yaml \
  -e ~/home/stack/network-environment.yaml \
  -e ~/heat-templates/environments/disable-telemetry.yaml \
  --validation-warnings-fatal \
  --ntp-server pool.ntp.org
```

2.1.4 Booting the VM

- To boot the VM on the undercloud machine, do the following:

1. Load the overcloudrc configuration.

   ```bash
   # source ./overcloudrc
   ```

2. Create a flavor.

   ```bash
   # openstack flavor create m1.small --id 3 --ram 2048 --disk 20 --vcpus 1
   ```

3. Create “cirrions” image.

   ```bash
   $ openstack image create --public --file cirros-mellanox_eth.img --disk-format qcow2 --container-format bare mellanox
   ```

4. Create a network.

   a. In the case of VLAN network:

   ```bash
   $ openstack network create private --provider-physical-network datacentre --provider-network-type vlan -share
   ```

   b. In the case of VXLAN network:
5. Create subnet.

```bash
$ openstack subnet create private_subnet --dhcp --network private --subnet-range 11.11.11.0/24
```

6. Boot a VM on the overcloud using the following command after creating the direct port accordingly.

- For the first VM:

```bash
$ direct_port1=`openstack port create direct1 --vnic-type=direct --network private --binding-profile '({"capabilities": ["switchdev"]})' | grep ' id ' | awk '{print $4}'`

$ openstack server create --flavor 3 --image mellanox --nic port-id=$direct_port1 vm1
```

- For the second VM:

```bash
$ direct_port2=`openstack port create direct2 --vnic-type=direct --network private --binding-profile '({"capabilities": ["switchdev"]})' | grep ' id ' | awk '{print $4}'`

$ openstack server create --flavor 3 --image mellanox --nic port-id=$direct_port2 vm2
```

### 2.2 Checking Hardware Offloading

To check whether or no hardware offloading is working, create two VMs: one on each compute node, as described below, and then use `tcpdump` on the representor port on the compute node to see if only two ICMP packets exist.

1. Use the Nova list to view the IP address created VMs from step 6 in section Error! Reference source not found.

```bash
$ count=1 | for i in `nova list | awk 'NR > 2 {print $12}' | cut -d'=' -f 2` ; do echo "VM$count=$i"; count=$(($count+1)) ; done
VM1=11.11.11.8
VM2=11.11.11.9
```

2. Ping from a VM to VM over two hypervisors in same network.
   a. On the first VM, run the ping command `ping <second_vm_ip_address>`. In the example below, 11.11.11.9 is used as the second VM IP address.

```bash
$ ping 11.11.11.9
PING 11.11.11.9 (11.11.11.9): 56 data bytes
64 bytes from 11.11.11.9: seq=0 ttl=64 time=65.600 ms
64 bytes from 11.11.11.9: seq=1 ttl=64 time=0.153 ms
64 bytes from 11.11.11.9: seq=2 ttl=64 time=0.109 ms
64 bytes from 11.11.11.9: seq=3 ttl=64 time=0.095 ms
64 bytes from 11.11.11.9: seq=4 ttl=64 time=0.121 ms
64 bytes from 11.11.11.9: seq=5 ttl=64 time=0.081 ms
64 bytes from 11.11.11.9: seq=6 ttl=64 time=0.121 ms
64 bytes from 11.11.11.9: seq=7 ttl=64 time=0.127 ms
64 bytes from 11.11.11.9: seq=8 ttl=64 time=0.123 ms
64 bytes from 11.11.11.9: seq=9 ttl=64 time=0.123 ms
```

b. On the compute node that contains the VM, identify the representor port used by the VM.

```bash
# ip link show enp3s0f0
```
6: enp3s0f0: <BROADCAST,MULTICAST,UP,LOWER_UP> mtu 1500 qdisc mq master ovs-system state UP mode DEFAULT group default qlen 1000
   link/ether ec:0d:9a:46:9e:84 brd ff:ff:ff:ff:ff:ff
   vf 0 MAC 00:00:00:00:00:00, spoof checking off, link-state enable, trust off, query_rss off
   vf 1 MAC 00:00:00:00:00:00, spoof checking off, link-state enable, trust off, query_rss off
   vf 2 MAC 00:00:00:00:00:00, spoof checking off, link-state enable, trust off, query_rss off
   vf 3 MAC fa:16:3e:b9:b8:ce, vlan 57, spoof checking on, link-state enable, trust off, query_rss off

#ls -l /sys/class/net/|grep eth
lrwxrwxrwx 1 root root 0 Sep 11 10:54 eth0 -> ../../devices/virtual/net/eth0
lrwxrwxrwx 1 root root 0 Sep 11 10:54 eth1 -> ../../devices/virtual/net/eth1
lrwxrwxrwx 1 root root 0 Sep 11 10:54 eth2 -> ../../devices/virtual/net/eth2
lrwxrwxrwx 1 root root 0 Sep 11 10:54 eth3 -> ../../devices/virtual/net/eth3

#sudo ovs-dpctl show
system@ovs-system:
   lookups: hit:1684 missed:1465 lost:0
   flows: 0
   masks: hit:8420 total:1 hit/pkt:2.67
   port 0: ovs-system (internal)
   port 1: br-enp3s0f0 (internal)
   port 2: br-int (internal)
   port 3: br-ex (internal)
   port 4: enp3s0f0
   port 5: tapfd274bb-61 (internal)
   port 6: qr-a73be843-4f (internal)
   port 7: qg-79a77e6d-8f (internal)
   port 8: qr-f55e4c5f-f3 (internal)
   port 9: eth3

c. Check that the hardware offloading rules are working using tcpdump on eth3 (the representor port).

   # tcpdump -i eth3 icmp
   tcpdump: verbose output suppressed, use -v or -vv for full protocol decode
   listening on eth3, link-type EN10MB (Ethernet), capture size 262144 bytes
   08:51:35.792856 IP 11.11.11.8 > 11.11.11.9: ICMP echo request, id 58113, seq 0, length 64
   08:51:35.858251 IP 11.11.11.9 > 11.11.11.8: ICMP echo reply, id 58113, seq 0, length 64
2.3 Verifying Hardware Offloading Configuration

1. Check that hardware offload is configured on the compute.
   
   ```bash
   # ovs-vsctl get Open_vSwitch . other_config:hw-offload "true"
   ```

2. Check the mode and inline-mode for the offloaded port for the ConectX-5 card.
   
   ```bash
   # devlink dev eswitch show pci/0000:03:00.0
   pci/0000:03:00.0: mode switchdev inline-mode none encap enable
   ```

3. Check if your version of ethtool support setting can enable TC offloads.
   
   ```bash
   # ethtool -k <interface_name>
   Features for <interface_name>:

hw-tc-offload: on
esp-hw-offload: off [fixed]
esp-tx-csum-hw-offload: off [fixed]
```
4. Reboot the compute node to make sure the VFs still exist to verify that the configuration of the switchdev is persistent.

```
# lspci | grep Mellanox
03:00.0 Ethernet controller: Mellanox Technologies MT27800 Family [ConnectX-5]
03:00.1 Ethernet controller: Mellanox Technologies MT27800 Family [ConnectX-5]
03:00.2 Ethernet controller: Mellanox Technologies MT27800 Family [ConnectX-5 Virtual Function]
03:00.3 Ethernet controller: Mellanox Technologies MT27800 Family [ConnectX-5 Virtual Function]
03:00.4 Ethernet controller: Mellanox Technologies MT27800 Family [ConnectX-5 Virtual Function]
03:00.5 Ethernet controller: Mellanox Technologies MT27800 Family [ConnectX-5 Virtual Function]
81:00.0 Ethernet controller: Mellanox Technologies MT27710 Family [ConnectX-4 Lx]
81:00.1 Ethernet controller: Mellanox Technologies MT27710 Family [ConnectX-4 Lx]
```

5. On the ComputeSriov node, check that the dumpxml on the compute node contains the VF port:

```
# virsh list
Id    Name                           State
----------------------------------------------------
1     instance-00000001              running
```

6. Check the dumpxml for the VF port.

```
# virsh dumpxml instance-00000001
<interface type='hostdev' managed='yes'>
    <mac address='fa:16:3e:57:ea:a2'/>
    <driver name='vfio'/>
    <source>
        <address type='pci' domain='0x0000' bus='0x03' slot='0x05' function='0x5'/>
    </source>
    <alias name='hostdev0'/>
    <address type='pci' domain='0x0000' bus='0x00' slot='0x04' function='0x0'/>
</interface>
```

### 2.4 Deploying TripleO with VF LAG Configuration

This feature is supported in kernel v5.0 RC and above.

1. Make sure the compute.yaml file has a Linux bond:

```
- type: linux_bond
  addresses:
  - ip_netmask:
      get_param: TenantIpSubnet
    name: bond0
  bonding_options:
    get_param: BondInterfaceOvsOptions
  members:
    - type: sriov_pf
      name:
        get_param: enp3s0f0
      link_mode: switchdev
```
2. Make sure the `/usr/share/openstack-tripleo-heat-templates/environments/ovs-hw-offload.yaml` file has VFs for the two ports of the Linux bond and hw-offloading enabled:

```
ComputeSriovParameters:
  NeutronSriovNumVFs: ["enp3s0f0:4:switchdev","enp3s0f1:4:switchdev"]
OvsHwOffload: True
```

3. Configure the bonding option in the same file.

```
parameter_defaults
  BondInterfaceOvsOptions: "mode=active-backup miimon=100"
```

The supported bonding mode for vf-lag are:
- Active-Backup
- Active-Active
- LACP

Below is an example of an uplink over a VLAN number 77 over a bond use:

```
- name: bond0.77
  addresses:
  - ip_netmask:
      get_param: TenantIpSubnet
    type: interface
  use_dhcp: false
```

Below is an example of an uplink of a general interface:

```
- type: interface
  name: enp2s0f1.70
  use_dhcp: false
  addresses:
  - ip_netmask:
      get_param: TenantIpSubnet
```
2.5 Deploy with GRE Tunnel Type

2.5.1 Network Cards Support Matrix and Limitations

The following Mellanox cards support the ASAP™ hardware-offloading feature:

<table>
<thead>
<tr>
<th>NICs</th>
<th>Supported Protocols</th>
<th>Supported Network Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>ConnectX®-5</td>
<td>Ethernet</td>
<td>Support hardware offloading over VLAN, VXLAN, and GER.</td>
</tr>
</tbody>
</table>

Use firmware version 16.24.1000 or newer for ConnectX-5 to support GRE hardware offloading.

2.5.2 Configuration

Starting from a fresh RHEL 7.5 bare metal server, install and configure the undercloud according to the official TripleO [installation documentation](#).

- Update `environments/ovs-hw-offload.yaml` to use GRE as Neutron tunnel type.

```
parameter_defaults:
  NeutronFlatNetworks: datacentre
  NeutronNetworkType: 'vlan,gre'
  NeutronTunnelTypes: 'gre'
```

2.5.3 Deploying the Overcloud

Deploy overcloud using the appropriate templates and yamls from `~/heat-templates` as described in [section 2.1.3](#).

2.5.4 Booting the VM

On the undercloud machine, do the following:

1. Load the overcloudrc configuration.
   ```bash
   # source overcloudrc
   ```

2. Create a flavor.
   ```bash
   # openstack flavor create m1.small --id 3 --ram 2048 --disk 20 --vcpus 1
   ```

3. Create “cirrios” image.
   ```bash
   $ openstack image create --public --file cirros-mellanox_eth.img --disk-format qcow2 --container-format bare mellanox
   ```

4. Create a network.
   ```bash
   $ openstack network create private --provider-network-type gre --share
   ```

5. Create subnet.
6. Boot a VM on the overcloud using the following command after creating the direct port accordingly.

- For the first VM:

```bash
$ direct_port1=`openstack port create direct1 --vnic-type=direct --network private --disable-port-security --binding-profile '{"capabilities": ["switchdev"]}' | grep ' id ' | awk '{print $4}'`

$ openstack server create --flavor 3 --image mellanox --nic port-id=$direct_port1 vm1
```

- For the second VM:

```bash
$ direct_port2=`openstack port create direct2 --vnic-type=direct --network private --disable-port-security --binding-profile '{"capabilities": ["switchdev"]}' | grep ' id ' | awk '{print $4}'`

$ openstack server create --flavor 3 --image mellanox --nic port-id=$direct_port2 vm2
```
3 NVMe over Fabrics (NVMe-oF)

3.1 Network Cards Support Matrix and Limitations

The following Mellanox network cards support the NVMe-oF feature:

<table>
<thead>
<tr>
<th>NICs</th>
<th>Supported Protocols</th>
</tr>
</thead>
<tbody>
<tr>
<td>ConnectX®-4</td>
<td>Ethernet</td>
</tr>
<tr>
<td>ConnectX®-4 Lx</td>
<td>Ethernet</td>
</tr>
<tr>
<td>ConnectX®-5</td>
<td>Ethernet</td>
</tr>
</tbody>
</table>

3.2 Deployment of Non-Containerized Overcloud

3.2.1 Configuration

Starting from a fresh RHEL 7.5 bare metal server, install and configure the undercloud according to the official TripleO installation documentation.

1. Install `nvmetcli` and `nvme-cli` packages on the image.
   ```bash
   virt-customize -x -v -a overcloud-full.qcow2 --run-command 'sudo yum install nvmetcli nvme-cli -y'
   ``

2. Upload the image.
   ```bash
   openstack overcloud image upload --image-path ~/ --update-existing
   ``

3. Change the `cinder-nvmeof-config.yaml` environment file (if needed).
   The `cinder-nvmeof-config.yaml` file contains the Cinder NVMe-oF backend parameters.

   ```bash
   vi ~/tripleo-heat-templates/environments/cinder-nvmeof-config.yaml
   ``

4. Prepare your deployment files as needed, then add the `cinder-nvmeof-config.yaml` environment file to your deployment script `cinder-nvmeof-config.yaml`.
   ```bash
   -e /home/stack/tripleo-heat-templates/environments/cinder-nvmeof-config.yaml
   ```

3.2.2 Deploying the NVMe-oF Overcloud

Deploy the overcloud using the appropriate templates and yamls from `~/heat-templates` as in the following example:

```bash
openstack overcloud deploy \
   --templates /home/stack/tripleo-heat-templates \
   -r /home/stack/roles_data.yaml \
   --libvirt-type kvm \
   --timeout 90 \
   -e /home/stack/cloud-names.yaml \
   -e /home/stack/tripleo-heat-templates/environments/network-isolation.yaml \
   -e /home/stack/tripleo-heat-templates/environments/net-single-nic-with-vlans.yaml \
   -e /home/stack/network-environment.yaml \
   -e /home/stack/enable-tls.yaml \
   -e /home/stack/tripleo-heat-templates/environments/tls-endpoints-public-ip.yaml \
   -e /home/stack/inject-trust-anchor.yaml
```
3.3 Deployment of Containerized Overcloud

3.3.1 Configuration

Starting from a fresh RHEL 7.5 bare metal server, install and configure the undercloud according to the official TripleO installation documentation.

1. Prepare the container images.

   ```
   ./overcloud-prep-containers.sh
   ```

2. Change the `cinder-nvmeof-config.yaml` environment file (if needed). The `cinder-nvmeof-config.yaml` file contains the Cinder NVMe-oF backend parameters.

   ```
   vi ~/tripleo-heat-templates/environments/cinder-nvmeof-config.yaml
   ```

3. Prepare deployment files as desired. Then add the `cinder-nvmeof-config.yaml` environment file to the deployment script `cinder-nvmeof-config.yaml`.

   ```
   -e ~/tripleo-heat-templates/environments/cinder-nvmeof-config.yaml
   ```

3.3.2 Deploying the NVMe-oF Overcloud

Deploy the overcloud using the appropriate templates and yamls from `~/heat-templates`, as in the following example:

```bash
openstack overcloud deploy \
  --templates /usr/share/openstack-tripleo-heat-templates \ 
  --libvirt-type kvm \ 
  --control-flavor oooq_control \ 
  --compute-flavor oooq_compute \ 
  --ceph-storage-flavor oooq_ceph \ 
  --block-storage-flavor oooq_blockstorage \ 
  --swift-storage-flavor oooq_objectstorage \ 
  --timeout 90 \ 
  -e /usr/share/openstack-tripleo-heat-templates/environments/docker.yaml\ 
  -e /home/stack/cloud-names.yaml \ 
  -e /home/stack/containers-default-parameters.yaml \ 
  -e /usr/share/openstack-tripleo-heat-templates/environments/network-isolation.yaml \ 
  -e /usr/share/openstack-tripleo-heat-templates/environments/net-single-nic-with-vlans.yaml \ 
  -e /home/stack/network-environment.yaml \ 
  -e /usr/share/openstack-tripleo-heat-templates/environments/low-memory-usage.yaml \ 
  -e /home/stack/enable-tls.yaml \ 
  -e /usr/share/openstack-tripleo-heat-templates/environments/tls-endpoints-public-ip.yaml \ 
  -e /home/stack/inject-trust-anchor.yaml \ 
  -e /usr/share/openstack-tripleo-heat-templates/environments/disable-telemetry.yaml \ 
  --validation-warnings-fatal
```
--ntp-server pool.ntp.org \
-e ~/nic_configs/network.yaml \
-e /usr/share/openstack-tripleo-heat-templates/environments/cinder-
   nvmeof-config.yaml \

4  Bare Metal Provision with BlueField

BlueField® SmartNIC adapters accelerate a wide range of applications through flexible data and control-plane offloading. Enabling a more efficient use of compute resources, BlueField adapters empower the CPU to focus on running applications rather than on networking or security processing. Additionally, as software-defined adapters, BlueField SmartNICs ensure the ultimate flexibility by adapting to future protocols and features through simple software updates.

4.1  Supported Features

Mellanox BlueField SmartNIC supports the following Features:

- Mellanox ASAP² Accelerated Switching and Packet Processing® for Open vSwitch (OVS) delivers flexible, highly efficient virtual switching and routing capabilities. OVS accelerations can be further enhanced using BlueField processing and memory. For example, the scale of OVS actions can be increased by utilizing BlueField internal memory, and more OVS actions and vSwitch/vRouter implementations can be supported.

- Network overlay technology (VXLAN) offload, including encapsulation and decapsulation, allows the traditional offloads to operate on the tunneled protocols, and offload Network Address Translation (NAT) routing capabilities.

4.2  Deploying Overcloud with Ironic

Starting from a fresh RHEL Bare Metal server, install and configure the undercloud according to the official TripleO installation documentation.

Follow [this link](#) for TripleO instructions to prepare bare metal overcloud.

1. Add provisioning network to network_data.yaml.

```yaml
- name: OcProvisioning
  vip: true
  name_lower: oc_provisioning
  vlan: 215
  ip_subnet: '172.16.4.0/24'
  allocation_pools: [{'start': '172.16.4.1', 'end': '172.16.4.2'}]
  ipv6_subnet: 'fd00:fd00:fd00:7000::/64'
  ipv6_allocation_pools: [{'start': 'fd00:fd00:fd00:7000::10', 'end': 'fd00:fd00:fd00:700 addresses 0:ffff:ffff:ffff:ffe'}]
  mtu: 1500
```

2. Add provisioning network to controller.yaml (under ovs_bridge mlnx-br config)

```yaml
vlan_id:
  get_param: OcProvisioningNetworkVlanID
ip_netmask:
  get_param: OcProvisioningIpSubnet
```

4.3  Preparing BlueField

1. Install the latest operating system on BlueField according to the [BlueField Installation Guide](#). Please use BFB RHEL 7.6 and above.
2. Check in the BlueField which uplink representor ports are present. Uplink Representor ports should be named pf0 and pf1.
   If the ports are not found, run the following:
   
   ```
   $ mst start
   $ mlxconfig -d /dev/mst/mt41682_pciconf0 s INTERNAL_CPU_MODEL=1
   $ reboot
   $ mlxconfig -d /dev/mst/mt41682_pciconf0 s ECPF_ESWITCH_MANAGER=1
   ECPF_PAGE_SUPPLIER=0
   ```

3. Install missing packages.
   Some important packages do not come with BlueField operating systems pre-installed.
   Run the following command to install the packages:
   ```
   $ yum install -y openvswitch
   ```

4. Install docker.
   OpenStack service runs as containers on BlueField. Run the following to install the docker:
   ```
   $ yum-config-manager --enable extras
   $ yum-config-manager --add-repo https://download.docker.com/linux/centos/docker-ce.repo
   $ yum install -y docker-ce docker-ce-cli containerd.io
   $ usermod -aG docker $(whoami)
   $ systemctl start docker.service
   $ systemctl enable docker.service
   ```

### 4.4 Creating Neutron Agent Container on BlueField

To run OpenStack service as a container, the image and a starting script will be required.

1. Updater /usr/lib/systemd/system/docker.service  docker.service ExecStart with the following:
   ```
   ExecStart=/usr/bin/dockerd --data-root /home/containers -H fd:// --
   containerd=/run/containerd/containerd.sock
   ```

2. Restart the docker service
   ```
   $ systemctl daemon-reload
   $ systemctl restart docker.service
   ```

3. Download container image at the following link: here and import the image to the docker repository:
   ```
   docker load -i centos-binary-neutron-openvswitch-agent.tar
   ```

4. Edit the script. This script is used to start the OpenStack service inside the container:
   ```
   $ vi /root/neutron_ovs_agent_launcher.sh
   ```
   and add the following lines:
   ```
   #!/bin/bash
   set +e
   /usr/bin/neutron-openvswitch-agent --config-file
   /etc/neutron/neutron.conf --config-file
   /etc/neutron/plugins/ml2/ml2_conf.ini --config-file
   /etc/neutron/plugins/ml2/openvswitch_agent.ini --log-
   file=/var/log/neutron/neutron.log
   ```

5. Create the container. Use the following script to create and start the container:
   ```
   LOG_DIR_HOST=/var/log/neutron
   CONF_DIR_HOST=/etc/neutron
   ```
4.5 Post-Deployment: Patch Neutron Server Container

After deployment, apply the Neutron Patch to the Neutron Server Container:

1. Get the patch file. Download the patch file from [here](#) and copy it to the Neutron server container.

2. Access the container bash shell.

   ```bash
   $ podman exec -u root -it neutron_api bash
   ```

3. Backup original files

   ```bash
   $ cd /usr/lib/python2.7/site-packages/neutron/
   $ cp agent/rpc.py agent/rpc.py.orig
   $ cp objects/ports.py objects/ports.py.orig
   $ cp plugins/ml2/plugin.py plugins/ml2/plugin.py.orig
   $ cp plugins/ml2/rpc.py plugins/ml2/rpc.py.orig
   ```

4. Apply the patch.

   ```bash
   $ cd /usr/lib/python2.7/site-packages/
   $ wget http://13.74.249.42/images/neutron_server_smartnic.patch
   $ git apply neutron_server_smartnic.patch
   ```

5. Restart the neutron api.

   ```bash
   $ podman restart neutron_api
   ```

4.6 BlueField Network Configuration

4.6.1 Network Configuration in BlueField

1. Create vlan interface with InternalApi vlan in BlueField.
   Inside the BlueField, create network script in `/etc/sysconfig/network-scripts/`

   ```bash
   vi /etc/sysconfig/network-scripts/ifcfg-p0.<InternalApi vlan>
   DEVICE=p0.<InternalApi vlan>
   BOOTPROTO=none
   ONBOOT=yes
   IPADDR=<InternalApi free IP>
   PREFIX=<InternalApi Subnet>
   ```
2. Add script to add Uplink representor to br-phys (bridge for vlan)

```bash
DEVICE=p0
TYPE=OVSPort
DEVICETYPE=ovs
OVS_BRIDGE=br-phys
ONBOOT=yes
```

The is required for the provision network which is usually flat or vlan network

3. Restart network service

```bash
$ systemctl restart network
```

4. Get Neutron configuration to the BlueField.

   a. Copy Neutron configuration from the controller to the BlueField in the
      `/var/lib/config-data/puppet-generated/neutron/etc/neutron/
      directory.

   b. Copy the following files to BlueField:
      ```
      /etc/neutron/neutron.conf
      /etc/neutron/plugins/ml2/ml2_conf.ini
      /etc/neutron/plugins/ml2/openvswitch_agent.ini
      ```

5. Update Neutron configuration.

   On the BlueField, changes must be made to set the correct values for the BlueField host.

   a. In file `/etc/neutron/neutron.conf`, change the following:
      ```
      bind_host=<Bluefield IP>
      host=<Bluefield hostname>
      ```

   b. In file `/etc/neutron/plugins/ml2/openvswitch_agent.ini` change the following:
      ```
      baremetal_smartnic=True
      ```

6. Update openvsiwtch with hw-offload enable

   ```
   $ systemctl enable openvswitch.service
   $ ovs-vsctl set Open_vSwitch . other_config:hw-offload=true
   $ systemctl restart openvswitch.service
   $ docker restart neutron_ovs_agent
   ```

### 4.6.2 Vlan Tenant Network Configuration in BlueField

1. In file `/etc/neutron/plugins/ml2/openvswitch_agent.ini` change the following:

   ```
   [securitygroup]
   firewall_driver=noop
   ```

   Please note that firewall driver is set to noop due to limitation that security group
   offload is not working on vlan network.

2. Restart neutron ovs agent

   ```
   $ systemctl restart openvswitch.service
   $ docker restart neutron_ovs_agent
   ```
### 4.6.3 VXLAN Tenant Network Configuration in BlueField

1. Create vlan interface with tenant vlan on Bluefiled
   
   Inside the BlueField, create network script in `/etc/sysconfig/network-scripts/`
   ```
   vi /etc/sysconfig/network-scripts/ifcfg-p0.<Tenant vlan>
   DEVICE=p0.<Tenant vlan>
   BOOTPROTO=none
   ONBOOT=yes
   IPADDR=<Tenant free IP>
   PREFIX=<Tenant Subnet>
   VLAN=yes
   ```

2. Restart network service
   ```
   $ systemctl restart network
   ```

3. In the BlueField edit `/etc/neutron/plugins/ml2/openvswitch_agent.ini` change the following:
   ```
   [ovs]
   local_ip=[BlueField vxlan tunnel ip]
   [agent]
   l2_population=True
   arp_responder=True
   [securitygroup]
   firewall_driver=openvswitch
   ```

4. In the BlueField - Restart neutron ovs agent
   ```
   $ systemctl restart openvswitch.service
   $ docker restart neutron_ovs_agent
   ```

5. In the Controller update `/var/lib/config-data/puppet-generated/neutron/etc/neutron/plugins/ml2/ml2_conf.ini`
   ```
   mechanism_drivers=openvswitch,l2population
   ```

6. In the Controller Restart the neutron api
   ```
   $ podman restart neutron_api
   ```

### 4.7 Overcloud images for BlueField BM Servers

1. Download the ironic images for BlueField from [here](#).

2. Download the following three files:
   - ironic-deploy.kernel
   - ironic-deploy.initramfs
   - bm_centos.qcow2

3. Add the images to the overcloud.
   ```
   openstack image create ironic-deploy-kernel --public --disk-format aki --container-format aki --file ./ironic-deploy.kernel
   openstack image create ironic-deploy-ram --public --disk-format ari --container-format ari --file ./ironic-deploy.initramfs
   openstack image create bm_centos --public --disk-format qcow2 --container-format bare --file ./bm_centos.qcow2
   ```
4.8 Create Overcloud Networks

A bare metal environment needs at least two networks: provisioning network and tenant network.

1. Create a provisioning network.

```
openstack network create --share --provider-network-type vlan --provider-
physical-network datacentre --provider-segment 215 provisioning
openstack subnet create --network provisioning --subnet-range
172.16.4.0/24 --gateway 172.16.4.6 --allocation-pool
start=172.16.4.201,end=172.16.4.250 provisioning-subnet
```

2. Open the following port in the default security group of the provisioning network.

```
ADMIN_SECURITY_GROUP_ID=$(openstack security group list --project admin -
-f value -c ID)
openstack security group rule create $(ADMIN_SECURITY_GROUP_ID) --
protocol udp --dst-port 67 --egress --description DHCP67
openstack security group rule create $(ADMIN_SECURITY_GROUP_ID) --
protocol udp --dst-port 68 --ingress --description DHCP68
openstack security group rule create $(ADMIN_SECURITY_GROUP_ID) --
protocol udp --dst-port 69 --egress --description TFTP69
openstack security group rule create $(ADMIN_SECURITY_GROUP_ID) --
protocol tcp --dst-port 6385 --egress --description Ironic6385
openstack security group rule create $(ADMIN_SECURITY_GROUP_ID) --
protocol tcp --dst-port 9999 --ingress --description Ironic9999
openstack security group rule create $(ADMIN_SECURITY_GROUP_ID) --
protocol tcp --dst-port 3260 --ingress --description IscsiDeploy3260
openstack security group rule create $(ADMIN_SECURITY_GROUP_ID) --
protocol tcp --dst-port 80 --egress --description DirectDeploy80
openstack security group rule create $(ADMIN_SECURITY_GROUP_ID) --
protocol tcp --dst-port 8088 --egress --description DirectDeploy8088
openstack security group rule create $(ADMIN_SECURITY_GROUP_ID) --
protocol tcp --dst-port 443 --egress --description DirectDeploy443
```

```
SERVICE_SECURITY_GROUP_ID=$(openstack security group list --project service -
-f value -c ID)
openstack security group rule create $(SERVICE_SECURITY_GROUP_ID) --
protocol udp --dst-port 67 --egress --description DHCP67
openstack security group rule create $(SERVICE_SECURITY_GROUP_ID) --
protocol udp --dst-port 68 --ingress --description DHCP68
openstack security group rule create $(SERVICE_SECURITY_GROUP_ID) --
protocol udp --dst-port 69 --egress --description TFTP69
openstack security group rule create $(SERVICE_SECURITY_GROUP_ID) --
protocol tcp --dst-port 6385 --egress --description Ironic6385
openstack security group rule create $(SERVICE_SECURITY_GROUP_ID) --
protocol tcp --dst-port 9999 --ingress --description Ironic9999
openstack security group rule create $(SERVICE_SECURITY_GROUP_ID) --
protocol tcp --dst-port 3260 --ingress --description IscsiDeploy3260
openstack security group rule create $(SERVICE_SECURITY_GROUP_ID) --
protocol tcp --dst-port 80 --egress --description DirectDeploy80
openstack security group rule create $(SERVICE_SECURITY_GROUP_ID) --
protocol tcp --dst-port 8088 --egress --description DirectDeploy8088
openstack security group rule create $(SERVICE_SECURITY_GROUP_ID) --
protocol tcp --dst-port 443 --egress --description DirectDeploy443
```

3. Create a tenant network.

```
openstack network create tenant-net
```
4.9 **Bare-Metal Flavor**

To create bare metal flavor, run the following command:

```bash
openstack flavor create --ram 1024 --disk 20 --vcpus 1 baremetal
openstack flavor set baremetal --property resources:CUSTOM_BAREMETAL=1
openstack flavor set baremetal --property resources:VCPU=0
openstack flavor set baremetal --property resources:MEMORY_MB=0
openstack flavor set baremetal --property resources:DISK_GB=0
```

4.10 **Add Bare-Metal Node**

1. Create `baremetal.yaml`:

```yaml
nodes:
  -
    name: node-1
    driver: ipmi
driver_info: null
    ipmi_address: host-ilo
    ipmi_username: admin
    ipmi_password: admin
    resource_class: baremetal
    network_interface: neutron
    properties: null
    cpu_arch: x86_64
cpu: 24
    memory_mb: 131072
capabilities: 'boot_option:local'
    ports:
      -
        address: '50:6b:4b:2f:0b:f4'
        pxe_enabled: true
        is_smartnic: true
        physical_network: datacentre
        local_link_connection:
          hostname: BF-BM
          port_id: pf0hpf
```

2. Create Baremetal Node

```bash
$ openstack baremetal node create -f baremetal.yaml
```

3. Specify the deploy kernel and deploy ramdisk on each node

```
KERNEL_UUID=`openstack image show bm-deploy-kernel -f value -c id`
INITRAMFS_UUID=`openstack image show bm-deploy-ramdisk -f value -c id`
openstack baremetal node set NODE_UUID --driver-info deploy_kernel=KERNEL_UUID --driver-info deploy_ramdisk=INITRAMFS_UUID
```

4. Set Node to available state

```
$ ironic node-set-provision-state node-1 manage
$ ironic node-set-provision-state node-1 provide
```

4.11 **Boot Bare Metal Instance**

To boot the bare metal instance, do the following:

```bash
openstack server create --flavor baremetal --image bm_centos --nic net-id=tenant-net node-1
```
5 Configuring Mellanox SDN Mechanism Driver Plugin Using TripleO

5.1 Configure and Prepare the NEO

Use the links below, to execute the necessary preliminary steps to prepare the NEO machine:
1. NEO introduction/installation.
2. Configure NTP on NEO machine.
   ```
   ssh root@<NEO_IP> ntpdate 0.asia.pool.ntp.org
   ```

5.2 Enable LLDP on Mellanox Switch

Enable LLDP on the Mellanox switch:
1. Login as admin.
2. Enter config mode.
   ```
   switch > enable
   switch # configure terminal
   ```
3. Enable LLDP globally on the switch.
   ```
   switch (config) # lldp
   ```

5.3 Install RPM Package on Container Image

Before deploying the overcloud, create `/home/stack/containers-prepare-parameter.yaml` in order to modify the container image with required package `python-networking-mlnx`.
1. Download the package rpm file `python2-networking-mlnx` from this repo.
2. Move the package to `/home/stack/rpm_path/` folder.
3. Generate `/home/stack/containers-prepare-parameter.yaml`, if it does not yet exist, using this command:
   ```
   (undercloud) [stack@undercloud ~]$ openstack tripleo container image prepare\   \default --local-push-destination \   --output-env-file /home/stack/containers-prepare-parameter.yaml
   ```
4. Modify the `/home/stack/containers-prepare-parameter.yaml` file to install the package on the container image.

Example:
```yaml
parameter_defaults:
  DockerInsecureRegistryAddress:
  - 192.168.24.1:8787
  ContainerImagePrepare:
  - push_destination: true
    set:
      tag: "current-tripleo-rdo"
      namespace: "docker.io/tripleostein"
```
5.4 Configure the Mellanox SDN Mechanism Driver Plugin

Modify the file `/usr/share/openstack-tripleo-heat-templates/environments/neutron-ml2-mlnx-sdn.yaml` in the following way:

```yaml
# A Heat environment file which can be used to configure Mellanox SDN
resource_registry:
OS::TripleO::Services::NeutronCorePlugin:
  OS::TripleO::Services::NeutronCorePluginMLNXSDN
parameter_defaults:
  MlnxSDNUsername: '<sdn_username>'
  MlnxSDNPassword: '<sdn_password>'
  MlnxSDNUrl: '<sdn_url>'
  MlnxSDNDomain: 'cloudx'
NeutronCorePlugin: 'neutron.plugins.ml2.plugin.Ml2Plugin'
NeutronMechanismDrivers: ['mlnx_sdn_assist','sriovnicswitch','openvswitch']
```

The domain name 'cloudx' and the SDN credentials need to be changed as required.

Add the file `/usr/share/openstack-tripleo-heat-templates/environments/neutron-ml2-mlnx-sdn.yaml` to the deploy command using `-e` parameter and deploy the overcloud.

Add the file `/home/stack/containers-prepare-parameter.yaml` to the deploy command using `-e` parameter and deploy the overcloud.
### 5.5 Set NTP Server

It is important that the time on the overcloud and NEO machine are synchronized.

In parameter defaults section, add the following line to set NTP server:

```yaml
parameter_defaults:
  NtpServer: ['0.asia.pool.ntp.org', '1.asia.pool.ntp.org']
```

NEO machine and overcloud nodes must have the same NTP servers.

### 5.6 Install LLDPAD Package to Overcloud Image

LLDPAD package must be installed on all overcloud nodes by installing the package on the overcloud image before deploying:

```bash
virt-customize --a overcloud-full.qcow2 --run-command \
  "sudo subscription-manager register --username <USERNAME> \ 
  --password <PASSWORD> --auto-attach; yum install lldpad -y ;\ 
  sudo subscription-manager unregister"
```

### 5.7 Configure LLDPAD in First Boot

1. Create file `first_boot.yaml` that contains the following content:

```yaml
heat_template_version: rocky
description: >
  Start and configure LLDPAD
resources:
  userdata:
    type: OS::Heat::MultipartMime
    properties:
      parts:
      - config: {get_resource: configure_lldp}
  configure_lldp:
    type: OS::Heat::SoftwareConfig
    properties:
      config: |
      #!/bin/bash
      set -eux
      set -o pipefail
      hostnamectl set-hostname $(hostname -s).localdomain
      hostnamectl set-hostname --transient $(hostname -s)
      sudo systemctl enable lldpad
      sudo systemctl start lldpad
      interface=p6p1
      lldptool set-lldp -i $interface adminStatus=rxtx
      lldptool -T -i $interface -V sysName enableTx=yes
      lldptool -T -i $interface -V portDesc enableTx=yes
      lldptool -T -i $interface -V sysDesc enableTx=yes
      lldptool -T -i $interface -V sysCap enableTx=yes
```
1. `lldptool -T -i $interface -V mngAddr enableTx=yes`
   `lldptool set-tlv -i $interface -V mngAddr ipv4=$(ip a sh br-ex | grep " inet " | head -1 | awk '{print $2}' | cut -d'/' -f1);
   outputs:
   OS::stack_id:
   value: {get_resource: userdata}

2. **In your** `network-environment.yaml` **add the following line:**

   ```yaml
   resource_registry:
   OS::TripleO::ComputeSriov::NodeUserData: ./first_boot.yaml
   ```
