## Definitions, Acronyms and Abbreviations

### Table 2: Definitions, Acronyms, and Abbreviations

<table>
<thead>
<tr>
<th>Term</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>SR-IOV</td>
<td>Single Root I/O Virtualization (SR-IOV) is a specification that allows a PCI device to appear virtually on multiple Virtual Machines (VMs), each of which has its own virtual function. This specification defines virtual functions (VFs) for the VMs and a physical function for the hypervisor. Using SR-IOV in a cloud infrastructure helps to achieve higher performance since traffic bypasses the TCP/IP stack in the kernel.</td>
</tr>
<tr>
<td>RoCE</td>
<td>RDMA over Converged Ethernet (RoCE) is a standard protocol which enables RDMA’s efficient data transfer over Ethernet networks allowing transport offload with hardware RDMA engine implementation, and superior performance. RoCE is a standard protocol defined in the InfiniBand Trade Association (IBTA) standard. RoCE makes use of UDP encapsulation allowing it to transcend Layer 3 networks. RDMA is a key capability natively used by the InfiniBand interconnect technology. Both InfiniBand and Ethernet RoCE share a common user API but have different physical and link layers.</td>
</tr>
<tr>
<td>ConnectX®-5</td>
<td>ConnectX-5 adapter cards support two ports of 100Gb/s Ethernet connectivity, sub-700 nanosecond latency, a very high message rate, and PCIe switch and NVMe over Fabric offloads, providing the highest performance and most flexible solution for the most demanding applications and markets. It uses Accelerated Switching and Packet Processing (ASAP²™) technology which enhances offloading of virtual switches and virtual routers, such as Open V-Switch (OVS), which results in significantly higher data transfer performance without overloading the CPU. Together with native RoCE and DPDK (Data Plane Development Kit) support, ConnectX-5 dramatically improves Cloud and NFV platform efficiency.</td>
</tr>
<tr>
<td>Open vSwitch (OVS)</td>
<td>Open vSwitch (OVS) allows Virtual Machines (VM) to communicate with each other and with the outside world. OVS traditionally resides in the hypervisor and switching is based on twelve tuples matching on flows. The OVS software-based solution is CPU intensive, affecting system performance and preventing fully utilizing available bandwidth.</td>
</tr>
<tr>
<td>OVS-DPDK</td>
<td>OVS-DPDK extends Open vSwitch performances while interconnecting with Mellanox DPDK Poll Mode Driver (PMD). It accelerates the hypervisor networking layer for better latency and higher packet rate while maintaining Open vSwitch data plane networking characteristics.</td>
</tr>
<tr>
<td>ASAP²</td>
<td>Mellanox ASAP²—Accelerated Switching And Packet Processing® technology allows to offload OVS by handling OVS data-plane in Mellanox ConnectX-5 (and onwards) NIC hardware (Mellanox Embedded Switch or eSwitch) while maintaining OVS control-plane unmodified. As a result, we observe significantly higher OVS performance without the associated CPU load. The current actions supported by ASAP² include packet parsing and matching, forward, drop along with VLAN push/pop or VXLAN encapsulated/decapsulated.</td>
</tr>
<tr>
<td>Term</td>
<td>Description</td>
</tr>
<tr>
<td>-----------</td>
<td>--------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>NVMEoF</td>
<td>NVMeOF or NVMe over Fabrics is a network protocol, like iSCSI, used to communicate between a host and a storage system over a network (a.k.a. fabric). It depends on and requires the use of RDMA. NVMeOF can use any of the RDMA technologies including InfiniBand and RoCE.</td>
</tr>

</table>
1 Mellanox OVS Hardware Offloading Support for TripleO

TripleO (OpenStack On OpenStack) is a program aimed at installing, upgrading, and operating OpenStack clouds using OpenStack’s own cloud facilities as the foundations, building on Nova, Neutron, and Heat to automate fleet management at datacenter scale.

Open vSwitch (OVS) allows Virtual Machines (VMs) to communicate with each other and with the outside world. OVS traditionally resides in the hypervisor and the switching is based on twelve-tuple matching on flows. The OVS software-based solution is CPU intensive, affecting system performance and prevents the full utilization of the available bandwidth. ASAP²—Accelerated Switching and Packet Processing® technology allows to offload OVS by handling the OVS data plane in Mellanox ConnectX-5 Network Interface Card (NIC) hardware (embedded switch or eSwitch) while leaving the control-plane of the OVS unmodified. As a result, the OVS performance significantly increases without the associated CPU load.

This Application Notes document details how to enable the Mellanox ASAP² technology feature of hardware-offloading support over OVS and OVN mechanism drivers.

1.1 Supported Features

TripleO Train supports the following features

- Networking Virtualization:
  - SR-IOV Legacy:
    - sriovnicswitch Mechanism driver
  - ASAP2:
    - with OVS mechanism driverASAP2 with OVN mechanism driverOVS over DPDK with inbox driver
    - SR-IOV InfiniBand with VMs
- Networking BareMetal:
  - Neutron OVS Agent on BlueField
  - Baremetal with InfiniBand
- Storage Virtualization:
  - NVMe over Fabric (NVMeOF)
  - iSER
1.2 System Requirements
The system requirements are detailed in the following table.

**Table 3: Undercloud Node Requirements**

<table>
<thead>
<tr>
<th>Platform</th>
<th>Type and Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>OS</td>
<td>Red Hat Enterprise Linux 7.7.</td>
</tr>
<tr>
<td>CPU</td>
<td>8-core 64-bit x86 processor with support for the Intel 64 or AMD64 CPU extensions.</td>
</tr>
<tr>
<td>Memory</td>
<td>Minimum 16 GB of RAM.</td>
</tr>
<tr>
<td>Disk Space</td>
<td>Minimum 40 GB of available disk space on the root disk. At least 10 GB of free space should be left before attempting an overcloud deployment or update. This free space accommodates image conversion and caching during the node provisioning process.</td>
</tr>
<tr>
<td>Networking</td>
<td>Minimum of 2 x 1Gb/s NICs. However, it is recommended to use a 10Gb/s interface for provisioning network traffic, especially if provisioning many nodes in the overcloud environment. Use Mellanox NIC for tenant network.</td>
</tr>
</tbody>
</table>

1.3 Supported Network Interface Cards and Firmware
Mellanox support for TripleO Train supports the following Mellanox NICs and their corresponding firmware versions:

<table>
<thead>
<tr>
<th>NIC</th>
<th>Supported Protocols</th>
<th>Recommended Firmware Rev.</th>
</tr>
</thead>
<tbody>
<tr>
<td>ConnectX-6</td>
<td>Ethernet/InfiniBand</td>
<td>20.26.1040</td>
</tr>
<tr>
<td>BlueField</td>
<td>Ethernet</td>
<td>18.25.1040</td>
</tr>
<tr>
<td>ConnectX®-5</td>
<td>Ethernet/InfiniBand</td>
<td>16.26.1040</td>
</tr>
<tr>
<td>ConnectX®-4 Lx</td>
<td>Ethernet</td>
<td>14.26.1040</td>
</tr>
<tr>
<td>ConnectX®-4</td>
<td>Ethernet/InfiniBand</td>
<td>12.26.1040</td>
</tr>
</tbody>
</table>

1.4 Supported Operating Systems
The following operating systems are the supported:

**Table 4: Supported Operating Systems**

<table>
<thead>
<tr>
<th>OS</th>
<th>Platform</th>
</tr>
</thead>
<tbody>
<tr>
<td>RHEL7.7</td>
<td>x86_64</td>
</tr>
</tbody>
</table>
1.5 Overcloud Operating System Versions

The following overcloud operating system versions are supported:

*Table 5: Overcloud Operating System Versions*

<table>
<thead>
<tr>
<th>Item</th>
<th>Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>Kernel</td>
<td>kernel-5.3.8-1.x86_64</td>

<td>kernel-headers-5.3.8-1.x86_64</td>
</tr>
<tr>
<td>Open vSwitch</td>
<td>openvswitch-2.12.1-1.el7.centos.x86_64</td>
</tr>
</tbody>
</table>
2 ASAP² Support

2.1 ASAP² Support Over Open vSwitch

2.1.1 Network Card Support Matrix and Limitations

The following Mellanox cards support ASAP² hardware offloading feature:

<table>
<thead>
<tr>
<th>NICs</th>
<th>Supported Protocols</th>
</tr>
</thead>
<tbody>
<tr>
<td>ConnectX-6</td>
<td>Ethernet</td>
</tr>
<tr>
<td>ConnectX®-5</td>
<td>Ethernet</td>
</tr>
</tbody>
</table>

2.1.2 Configuration

Starting from a fresh RHEL 7.7 bare metal server, install and configure the undercloud according to the official TripleO installation documentation.

1. Use the `ovs-hw-offload.yaml` file from the following location:

   ```
   /usr/share/openstack-tripleo-heat-templates/environments/ovs-hw-offload.yaml
   ```

   Configure it over VLAN/VXLAN setup in the following way:

   a. In the case of a VLAN setup, configure the `ovs-hw-offload.yaml`:

   ```
   # A Heat environment file that enables OVS Hardware Offload in the overcloud.
   # This works by configuring SR-IOV NIC with switchdev and OVS Hardware Offload on
   # compute nodes. The feature supported in OVS 2.8.0

   parameter_defaults:
   - NeutronFlatNetworks: datacentre
   - NeutronNetworkType:
     - vlan
   - NeutronTunnelTypes: ''

   NovaSchedulerDefaultFilters:

   NovaSchedulerAvailableFilters:
   ['nova.scheduler.filters.all_filters','nova.scheduler.filters.pci_pass through_filter.PciPassthroughFilter']

   NovaPCIPassthrough:
   - devname: <interface_name>
     physical_network: datacentre

   # Mapping of SR-IOV PF interface to neutron physical_network.
   # # In case of Vxlan/GRE physical_network should be null.
   # # In case of flat/vlan the physical_network should as configured in neutron.

   ComputeSriovParameters:
   - NeutronBridgeMappings:
     - datacentre:br-ex
   - OvsHwOffload: True
   ```
b. In the case of a VXLAN setup, do the following:

i. Configure the `ovs-hw-offload.yaml`:

```yaml
# A Heat environment file that enables OVS Hardware Offload in the overcloud.
# This works by configuring SR-IOV NIC with switchdev and OVS Hardware Offload on
# compute nodes. The feature supported in OVS 2.8.0

parameter_defaults:
  NeutronFlatNetworks: datacentre

NovaSchedulerDefaultFilters:

NovaSchedulerAvailableFilters:
  ['nova.scheduler.filters.all_filters','nova.scheduler.filters.pciPassthroughFilter']

NovaPCIPassthrough:
  - devname: <interface_name>
    physical_network: null
    # Mapping of SR-IOV PF interface to neutron physical_network.
    # In case of Vxlan/GRE physical_network should be null.
    # In case of flat/vlan the physical_network should as configured in
    # neutron.

ComputeSriovParameters:
  NeutronBridgeMappings:
  - datacentre:br-ex
  OvsHwOffload: True

ii. Configure the interface names in the `/usr/share/openstack-tripleo-heat-templates/network/config/single-nic-vlans/control.yaml` files by adding the following code to move the tenant network from VLAN on a bridge to be on a separated interface.

```yaml
- type: interface
  name: <interface_name>
  addresses:
    - ip_netmask: get_param: TenantIpSubnet
```  

iii. Configure the interface names in the `/usr/share/openstack-tripleo-heat-templates/network/config/single-nic-vlans/compute.yaml` files by adding the following code to move the tenant network from VLAN on a bridge to be on a separated interface.

```yaml
- type: sriov_pf
  name:
    get_param: enp3s0f0
  link_mode: switchdev
  numvfs: 64
  promisc: true
  use_dhcp: false
```

2. Create a new role for the compute node and change it to ComputeSriov.

```bash
# openstack overcloud roles generate -o roles_data.yaml Controller ComputeSriov
```

3. Update the `~/cloud-names.yaml` accordingly.

See the following example:
parameter_defaults:
ComputeSriovCount: 2
OvercloudComputeSriovFlavor: compute

4. Assign the compute.yaml file to the ComputeSriov role. Update the ~/heat-templates/environments/net-single-nic-with-vlans.yaml file by adding the following line:

OS::TripleO::ComputeSriov::Net::SoftwareConfig: ..network/config/single-nic-vlans/compute.yaml

5. Run overcloud-prep-containers.sh

2.1.3 Deploying the Overcloud

Deploy the overcloud using the appropriate templates and yamls from ~/heat-templates as in the following example:

openstack overcloud deploy
--templates ~/heat-templates
--libvirt-type kvm -r ~/roles_data.yaml
-e /home/stack/containers-default-parameters.yaml
-e ~/heat-templates/environments/docker.yaml
-e ~/heat-templates/environments/ovs-hw-offload.yaml
--control-flavor oooq_control
--compute-flavor oooq_compute
--ceph-storage-flavor oooq_ceph
--block-storage-flavor oooq_blockstorage
--swift-storage-flavor oooq_objectstorage
--timeout 90
-e /home/stack/cloud-names.yaml
-e ~/heat-templates/environments/network-isolation.yaml
-e ~/heat-templates/environments/net-single-nic-with-vlans.yaml
-e /home/stack/network-environment.yaml
-e ~/heat-templates/environments/disable-telemetry.yaml
--validation-warnings-fatal
--ntp-server pool.ntp.org

2.1.4 Booting the VM

- To boot the VM on the undercloud machine, do the following:

1. Load the overcloudrc configuration.
   
   # source ./overcloudrc

2. Create a flavor.

   # openstack flavor create m1.small --id 3 --ram 2048 --disk 20 --vcpus 1

3. Create “cirrinos” image.

   $ openstack image create --public --file cirrinos-mellanox_eth.img --disk-format qcow2 --container-format bare mellanox

4. Create a network.

   a. In the case of VLAN network:

      $ openstack network create private --provider-physical-network datacentre --provider-network-type vlan -share

   b. In the case of VXLAN network:

      $ openstack network create private --provider-network-type vxlan -share

5. Create subnet.

   $ openstack subnet create private_subnet --dhcp --network private --subnet-range 11.11.11.0/24
6. Boot a VM on the overcloud using the following command after creating the direct port accordingly.

- For the first VM:

```bash
$ direct_port1=`openstack port create direct1 --vnic-type=direct --network private --binding-profile '{"capabilities": ["switchdev"]}' | grep ' id ' | awk '{print $4}'`

$openstack server create --flavor 3 --image mellanox --nic port-id=$direct_port1 vm1
```

- For the second VM:

```bash
$ direct_port2=`openstack port create direct2 --vnic-type=direct --network private --binding-profile '{"capabilities": ["switchdev"]}' | grep ' id ' | awk '{print $4}'`

$ openstack server create --flavor 3 --image mellanox --nic port-id=$direct_port2 vm2
```

### 2.2 Checking Hardware Offloading

To check whether or not hardware offloading is working, create two VMs: one on each compute node, as described below, and then use `tcpdump` on the representor port on the compute node to see if only two ICMP packets exist.

1. Use the Nova list to view the IP address created VMs from step 6 in section **Error! Reference source not found.**.

```bash
$ count=1 | for i in `nova list | awk 'NR > 2 {print $12}' | cut -d '=' -f 2` ; do echo "$VM$count=$i"; count=$(($count+1)) ; done
VM1=11.11.11.8
VM2=11.11.11.9
```

2. Ping from a VM to VM over two hypervisors in same network.

   a. On the first VM, run the ping command `ping <second_vm_ip_address>`. In the example below, 11.11.11.9 is used as the second VM IP address.

```bash
$ ping 11.11.11.9
PING 11.11.11.9 (11.11.11.9): 56 data bytes
64 bytes from 11.11.11.9: seq=0 ttl=64 time=65.600 ms
64 bytes from 11.11.11.9: seq=1 ttl=64 time=0.153 ms
64 bytes from 11.11.11.9: seq=2 ttl=64 time=0.109 ms
64 bytes from 11.11.11.9: seq=3 ttl=64 time=0.095 ms
64 bytes from 11.11.11.9: seq=4 ttl=64 time=0.121 ms
64 bytes from 11.11.11.9: seq=5 ttl=64 time=0.081 ms
64 bytes from 11.11.11.9: seq=6 ttl=64 time=0.121 ms
64 bytes from 11.11.11.9: seq=7 ttl=64 time=0.127 ms
64 bytes from 11.11.11.9: seq=8 ttl=64 time=0.123 ms
64 bytes from 11.11.11.9: seq=9 ttl=64 time=0.123 ms
```

   b. On the compute node that contains the VM, identify the representor port used by the VM.

```bash
# ip link show enp3s0f0
6: enp3s0f0: <BROADCAST,MULTICAST,UP,LOWER_UP> mtu 1500 qdisc mq master ovs-system state UP mode DEFAULT group default qlen 1000
   link/ether ec:0d:9a:46:9e:84 brd ff:ff:ff:ff:ff:ff
   vf 0 MAC 00:00:00:00:00:00, spoof checking off, link-state enable, trust off, query_rss off
   vf 1 MAC 00:00:00:00:00:00, spoof checking off, link-state enable, trust off, query_rss off
   vf 2 MAC 00:00:00:00:00:00, spoof checking off, link-state enable, trust off, query_rss off
```
vf 3 MAC fa:16:3e:b9:b8:ce, vlan 57, spoof checking on, link-state enable, trust off, query_rss off

# ls -l /sys/class/net/ | grep eth
lrwxrwxrwx 1 root root 0 Sep 11 10:54 eth0 -> ../../devices/virtual/net/eth0
lrwxrwxrwx 1 root root 0 Sep 11 10:54 eth1 -> ../../devices/virtual/net/eth1
lrwxrwxrwx 1 root root 0 Sep 11 10:54 eth2 -> ../../devices/virtual/net/eth2
lrwxrwxrwx 1 root root 0 Sep 11 10:54 eth3 -> ../../devices/virtual/net/eth3

# sudo ovs-dpctl show

system@ovs-system:
lookups: hit:1684 missed:1465 lost:0
flows: 0
masks: hit:8420 total:1 hit/pkt:2.67
port 0: ovs-system (internal)
port 1: br-enp3s0f0 (internal)
port 2: br-int (internal)
port 3: br-ex (internal)
port 4: enp3s0f0
port 5: tapfdc744bb-61 (internal)
port 6: qr-a7ble843-4f (internal)
port 7: qg-79a77e6d-8f (internal)
port 8: qr-f55e4c5f-f3 (internal)
port 9: eth3

c. Check that the hardware offloading rules are working using tcpdump on eth3 (the representor port).

# tcpdump -i eth3 icmp
tcpdump: verbose output suppressed, use -v or -vv for full protocol decode
listening on eth3, link-type EN10MB (Ethernet), capture size 262144 bytes
08:51:35.792856 IP 11.11.11.8 > 11.11.11.9: ICMP echo request, id 58113, seq 0, length 64
08:51:35.858251 IP 11.11.11.9 > 11.11.11.8: ICMP echo reply, id 58113, seq 0, length 64
2.3 Verifying Hardware Offloading Configuration

1. Check that hardware offload is configured on the compute.

   ```
   # ovs-vsctl get Open_vSwitch . other_config:hw-offload "true"
   ```

2. Check the mode and inline-mode for the offloaded port for the ConectX-5 card.

   ```
   # devlink dev eswitch show pci/0000:03:00.0
   pci/0000:03:00.0: mode switchdev inline-mode none encap enable
   ```

3. Check if your version of ethtool support setting can enable TC offloads.

   ```
   # ethtool -k <interface_name>
   ```

   tx-vlan-stag-hw-insert: off [fixed]
   tx-vlan-stag-hw-parse: off [fixed]
   tx-vlan-stag-filter: off [fixed]
   l2-fwd-offload: off [fixed]
   hw-tc-offload: on
   esp-hw-offload: off [fixed]
   esp-tx-csum-hw-offload: off [fixed]
   ```

4. Reboot the compute node to make sure the VFs still exist to verify that the configuration of the switchdev is persistent.
5. On the ComputeSriov node, check that the `dumpxml` on the compute node contains the VF port:

```bash
# virsh list
Id       Name                        State
----------------------------------------
1         instance-00000001          running
```

6. Check the `dumpxml` for the VF port.

```bash
# virsh dumpxml instance-00000001
<interface type='hostdev' managed='yes'>
  <mac address='fa:16:3e:57:ea:a2'/>
  <driver name='vfio'/>
  <source>
    <address type='pci' domain='0x0000' bus='0x03' slot='0x00' function='0x5'/>
  </source>
  <alias name='hostdev0'/>
  <address type='pci' domain='0x0000' bus='0x00' slot='0x04' function='0x0'/>
</interface>
```

### 2.4 Deploying TripleO with VF LAG Configuration

This feature is supported in kernel v5.0 RC and above.

1. Make sure the `compute.yaml` file has a Linux bond:

```yaml
- type: linux_bond
  addresses:
  - ip_netmask:
    get_param: TenantIpSubnet
  name: bond0
  bonding_options:
    get_param: BondInterfaceOvsOptions
  members:
  - type: sriov_pf
    name:
    get_param: enp3s0f0
    link_mode: switchdev
    numvfs: 64
    promisc: true
    use_dhcp: false
  - type: sriov_pf
    name:
```
2. Make sure the `/usr/share/openstack-tripleo-heat-templates/environments/ovs-hw-offload.yaml` file has VF for the two ports of the Linux bond and hw-offloading enabled:

   ```yaml
   get_param: enp3s0f1
   link_mode: switchdev
   numvfs: 64
   promisc: true
   use_dhcp: false
   ``

3. Configure the bonding option in the same file.

   ```yaml
   parameter_defaults
   BondInterfaceOvsOptions: "mode=active-backup miimon=100"
   ``

The supported bonding mode for vf-lag are:

- Active-Backup
- Active-Active
- LACP

Below is an example of an uplink over a VLAN number 77 over a bond use:

```yaml
- name: bond0.77
  addresses:
  - ip_netmask: 
    get_param: TenantIpSubnet
  type: interface
  use_dhcp: false
```

Below is an example of an uplink of a general interface:

```yaml
- type: interface
  name: enp2s0f1.70
  use_dhcp: false
  addresses:
  - ip_netmask:
    get_param: TenantIpSubnet
```
2.5 Deploy with GRE Tunnel Type

2.5.1 Network Cards Support Matrix and Limitations

The following Mellanox cards support the ASAP² hardware-offloading feature:

<table>
<thead>
<tr>
<th>NICs</th>
<th>Supported Protocols</th>
<th>Supported Network Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>ConnectX®-5</td>
<td>Ethernet</td>
<td>Support hardware offloading over VLAN, VXLAN, and GER.</td>
</tr>
</tbody>
</table>

Use firmware version 16.24.1000 or newer for ConnectX-5 to support GRE hardware offloading.

2.5.2 Configuration

Starting from a fresh RHEL 7.7 bare metal server, install and configure the undercloud according to the official TripleO installation documentation.

4. Update `enviroments/ovs-hw-offload.yaml` to use GRE as Neutron tunnel type.

   ```yaml
   parameter_defaults:
     NeutronFlatNetworks: datacentre
     NeutronNetworkType: 'vlan,gre'
     NeutronTunnelTypes: 'gre'
   ```

2.5.3 Deploying the Overcloud

Deploy overcloud using the appropriate templates and yamls from `~/heat-templates` as described in section 2.1.3.

2.5.4 Booting the VM

On the undercloud machine, do the following:

5. Load the `overcloudrc` configuration.
   ```bash
   # source overcloudrc
   ```

6. Create a flavor.
   ```bash
   # openstack flavor create m1.small --id 3 --ram 2048 --disk 20 --vcpus 1
   ```

7. Create “cirrios” image.
   ```bash
   $ openstack image create --public --file cirros-mellanox_eth.img --disk-format qcow2 --container-format bare mellanox
   ```

8. Create a network.
   ```bash
   $ openstack network create private --provider-network-type gre --share
   ```

9. Create subnet.
$ openstack subnet create private_subnet --dhcp --network private --subnet-range 11.11.11.0/24

10. Boot a VM on the overcloud using the following command after creating the direct port accordingly.

- For the first VM:

```bash
$ direct_port1=`openstack port create direct1 --vnic-type=direct --network private --disable-port-security --binding-profile '
{"capabilities":["switchdev"]}' | grep ' id ' | awk '{print $4}'`
$openstack server create --flavor 3 --image mellanox --nic port-id=$direct_port1 vm1
```

- For the second VM:

```bash
$ direct_port2=`openstack port create direct2 --vnic-type=direct --network private --disable-port-security --binding-profile '
{"capabilities":["switchdev"]}' | grep ' id ' | awk '{print $4}'`
$ openstack server create --flavor 3 --image mellanox --nic port-id=$direct_port2 vm2
```
3 NVMe over Fabrics (NVMe-oF)

3.1 Network Cards Support Matrix and Limitations

The following Mellanox network cards support the NVMe-oF feature:

<table>
<thead>
<tr>
<th>NICs</th>
<th>Supported Protocols</th>
</tr>
</thead>
<tbody>
<tr>
<td>ConnectX®-6</td>
<td>Ethernet</td>
</tr>
<tr>
<td>ConnectX®-5</td>
<td>Ethernet</td>
</tr>
<tr>
<td>ConnectX®-4 Lx</td>
<td>Ethernet</td>
</tr>
<tr>
<td>ConnectX®-4</td>
<td>Ethernet</td>
</tr>
</tbody>
</table>

3.2 Deployment of Containerized Overcloud

3.2.1 Configuration

Starting from a fresh RHEL 7.7 bare metal server, install and configure the undercloud according to the official TripleO [installation documentation](#).

1. Prepare the container images.

   ```bash
   ./overcloud-prep-containers.sh
   ```

2. Change the `cinder-nvmeof-config.yaml` environment file (if needed).

   ```bash
   vi ~/tripleo-heat-templates/environments/cinder-nvmeof-config.yaml
   ```

3. Prepare deployment files as desired. Then add the `cinder-nvmeof-config.yaml` environment file to the deployment script `cinder-nvmeof-config.yaml`.

   ```bash
   -e /home/stack/tripleo-heat-templates/environments/cinder-nvmeof-config.yaml
   ```

3.2.2 Deploying the NVMe-oF Overcloud

Deploy the overcloud using the appropriate templates and yamls from `~/heat-templates`, as in the following example:

```bash
openstack overcloud deploy \
   --templates /usr/share/openstack-tripleo-heat-templates \
   --libvirt-type kvm \
   --control-flavor oooq_control \
   --compute-flavor oooq_compute \
   --block-storage-flavor oooq_ceph \
   --swift-storage-flavor oooq_objectstorage \
   --timeout 90 \
   -e /usr/share/openstack-tripleo-heat-templates/environments/docker.yaml\n   -e /home/stack/cloud-names.yaml \
   -e /home/stack/containers-default-parameters.yaml \
   -e /usr/share/openstack-tripleo-heat-templates/environments/network-isolation.yaml \n   -e /usr/share/openstack-tripleo-heat-templates/environments/net-single-nic-with-vlans.yaml \
   -e /home/stack/network-environment.yaml \
   -e /usr/share/openstack-tripleo-heat-templates/environments/low-memory-usage.yaml \n   -e /home/stack/enable-tls.yaml\n```
-e /usr/share/openstack-tripleo-heat-templates/environments/tls-endpoints-public-ip.yaml \
-e /home/stack/inject-trust-anchor.yaml \
-e /usr/share/openstack-tripleo-heat-templates/environments/disable-telemetry.yaml \
    --validation-warnings-fatal \
    --ntp-server pool.ntp.org \
-e ~/nic_configs/network.yaml \
-e /usr/share/openstack-tripleo-heat-templates/environments/cinder-nvmeof-config.yaml \

4 Bare Metal Provision with BlueField

BlueField® SmartNIC adapters accelerate a wide range of applications through flexible data and control-plane offloading. Enabling a more efficient use of compute resources, BlueField adapters empower the CPU to focus on running applications rather than on networking or security processing. Additionally, as software-defined adapters, BlueField SmartNICs ensure the ultimate flexibility by adapting to future protocols and features through simple software updates.

4.1 Supported Features

Mellanox BlueField SmartNIC supports the following Features:

- Mellanox ASAP²—Accelerated Switching and Packet Processing® for Open vSwitch (OVS) delivers flexible, highly efficient virtual switching and routing capabilities. OVS accelerations can be further enhanced using BlueField processing and memory. For example, the scale of OVS actions can be increased by utilizing BlueField internal memory, and more OVS actions and vSwitch/vRouter implementations can be supported.

- Network overlay technology (VXLAN) offload, including encapsulation and decapsulation, allows the traditional offloads to operate on the tunneled protocols, and offload Network Address Translation (NAT) routing capabilities.

4.2 Preparing BlueField

1. Install the latest operating system on BlueField according to the BlueField Installation Guide.

2. Validate representor ports presence.

3. Check in the BlueField which representor ports are present. Representor ports should be named pf0.
   If the ports are not found, run the following:
   ```
   $ mst start
   $ mlxconfig -d /dev/mst/mt41682_pciconf0 s INTERNAL_CPU_MODEL=1
   $ mlxconfig -d /dev/mst/mt41682_pciconf0 s ECPF_ESWITCH_MANAGER=1
   ECPF_PAGE_SUPPLIER=0
   ```

4. Install missing packages.
   Some important packages do not come with BlueField operating systems pre-installed. Run the following command to install the packages:
   ```
   $ yum install -y openvswitch
   ```

5. Install docker.
   OpenStack service runs as containers on BlueField. Run the following to install the docker:
   ```
   $ yum-config-manager --enable extras
   $ yum-config-manager --add-repo
   https://download.docker.com/linux/centos/docker-ce.repo
   $ yum install -y docker-ce docker-ce-cli containerd.io
   $ usermod -aG docker $(whoami)
   $ systemctl start docker.service
   $ systemctl enable docker.service
   ```
4.3 Creating Neutron Agent Container on BlueField

To run OpenStack service as a container, the image and a starting script will be required.

1. Download container image at the following link: [here](#) and import the image to the docker repository:

```
docker load -i centos-binary-neutron-openvswitch-agent.tar
```

2. Start the script. This script is used to start the OpenStack service inside the container:

```
$ vi /root/neutron_ovs_agent_launcher.sh
```

and add the following lines:

```
#!/bin/bash
set -xe
/usr/bin/neutron-openvswitch-agent --config-file /etc/neutron/neutron.conf --config-file /etc/neutron/plugins/ml2/ml2_conf.ini --config-file /etc/neutron/plugins/ml2/openvswitch_agent.ini --log-file=/var/log/neutron/neutron.log
```

3. Create the container. Use the following script to create and start the container:

```
LOG_DIR_HOST=/var/log/neutron
CONF_DIR_HOST=/etc/neutron
IMAGE_ID=c47985e0fbad
CONTAINER_NAME=neutron_ovs_agent

# Create log folder and grant permissions
mkdir -p $LOG_DIR_HOST
chmod -R 755 $LOG_DIR_HOST

# Create container
docker container create \
--network host \
--privileged \
--name $CONTAINER_NAME \
--restart unless-stopped \
-v /run/openvswitch:/run/openvswitch/ \
-v $LOG_DIR_HOST:/var/log/neutron \
-v $CONF_DIR_HOST:/etc/neutron \
-v /root/neutron_ovs_agent_launcher.sh:/neutron_ovs_agent_launcher.sh \
$IMAGE_ID \
bash /neutron_ovs_agent_launcher.sh

# Start container
docker start $CONTAINER_NAME
```

4.4 Deployment of TripleO with Bare-Metal Service

Starting from a fresh RHEL 7.7 bare metal server, install and configure the undercloud according to the official TripleO installation documentation.

Follow [this link](#) for TripleO instructions to prepare bare metal overcloud.

4.5 BlueField Network Configuration

4.5.1 Network Configuration in BlueField

1. Set static IP to the BlueField from the overcloud external network subnet.

   Inside the BlueField, create network script in `/etc/sysconfig/network-scripts/` to create the external network interface, make sure the IP is free and the gateway is the controller IP.
vi /etc/sysconfig/network-scripts/ifcfg-enp3s0f1
# Generated by dracut initrd
NAME="enp3s0f1"
ONBOOT=yes
NETBOOT=yes
IPV6INIT=no
BOOTPROTO=static
IPADDR=192.168.24.111
NETMASK=255.255.255.0
GATEWAY=192.168.24.30
DEFROUTE=yes
DEVICE=enp3s0f1
TYPE=Ethernet

2. Add an external bridge.

In BlueField, the operator must manually add the external bridge and its relevant interface.

$ ovs-vsctl add-br br-ext
$ ovs-vsctl add-port br-ext enp3s0f0

3. Get Neutron configuration to the BlueField.

a. Copy Neutron configuration from the controller to the BlueField in the /var/lib/config-data/puppet-generated/neutron/ directory.

b. Copy the following files to BlueField:

   etc/neutron/neutron.conf
   etc/neutron/plugins/ml2/ml2_conf.ini
   etc/neutron/plugins/ml2/openvswitch_agent.ini

4. Update Neutron configuration.

On the BlueField, changes must be made to set the correct values for the BlueField host.

a. In file /etc/neutron/neutron.conf, change the following:

   bind_host=<Bluefield IP>
   host=<Bluefield host>

b. In file /etc/neutron/plugins/ml2/ml2_conf.ini, change the following:

   local_ip=<Bluefield IP>
   firewall_driver=noop

5. Install the correct version of python-ironicclient to support SmartNIC port-creation.

On the undercloud, run:

   sudo yum install python2-ironicclient

4.6 Add BlueField Ironic Images

1. Download the ironic images for BlueField from here.

2. Download the following three files:

   • ironic-deploy.kernel
   • ironic-deploy.initramfs
   • bm_centos.qcow2

3. Add the images to the overcloud.

   openstack image create ironic-deploy-kernel --public --disk-format ari -- container-format ari --file . /ironic-deploy.kernel
   openstack image create ironic-deploy-ram --public --disk-format ari -- container-format ari --file . /ironic-deploy.initramfs
4.7 Create Overcloud Networks

A bare metal environment needs at least two networks: provisioning network and tenant network.

4. Create a provisioning network.

```bash
openstack network create --share --provider-network-type flat
--provider-physical-network datacentre --external provisioning
openstack subnet create --network provisioning
--subnet-range 192.168.24.0/24 --gateway 192.168.24.40
--allocation-pool start=192.168.24.41,end=192.168.24.100
provisioning-subnet
```

5. Create a tenant network.

```bash
openstack network create tenant-net
openstack subnet create --network tenant-net --subnet-range 192.0.3.0/24
--allocation-pool start=192.0.3.10,end=192.0.3.20 tenant-subnet
```
4.8  **Bare-Metal Flavor**

To create bare metal flavor, run the following command:

```bash
openstack flavor create --ram 1024 --disk 20 --vcpus 1 baremetal
openstack flavor set baremetal --property resources:CUSTOM_BAREMETAL=1
openstack flavor set baremetal --property resources:VCPU=0
openstack flavor set baremetal --property resources:MEMORY_MB=0
openstack flavor set baremetal --property resources:DISK_GB=0
```

4.9  **Disable Automated Cleaning for Ironic**

1. Login to the overcloud controller and edit **ironic.conf** file and set
   ```
   automated_clean=False
   ```

2. Restart ironic conductor container:
   ```
   $ sudo docker restart ironic_conductor
   ```

4.10  **Add Bare-Metal Node**

Use the following script to add the bare metal nodes. Set the variables values (HOST_NAME, BM_NAME, IPMI_IP, BF_MAC):

```bash
#!/bin/bash -xe
. overcloudrc
export HOST_NAME=r-dcs81-005
export BM_NAME=r-dcs81-bf
export IPMI_IP=10.209.226.164
export BF_MAC=50:6b:4b:34:a5:3a
export KERNEL=$(glance image-list|grep ironic-deploy-kernel|awk '{print $2}')
export RAM=$(glance image-list|grep ironic-deploy-ram|awk '{print $2}')
openstack baremetal node create --network-interface neutron --name $BM_NAME
  --driver ipmi --driver-info ipmi_address=$IPMI_IP --driver-info
  ipmi_password=ADMIN --driver-info ipmi_username=ADMIN --resource-class
  baremetal --driver-info deploy_kernel=$KERNEL --driver-info
  deploy_ramdisk=$RAM
#ironic node-update $BM_NAME replace boot_interface=ipxe
ironic node-update $BM_NAME replace deploy_interface=direct
ironic node-update $BM_NAME add properties/capabilities="boot_option:local"
openstack --os-baremetal-api-version 1.21 baremetal node set $BM_NAME --resource-class baremetal
nova flavor-key baremetal set capabilities:boot_option="local" 2>&1|tee >
/dev/null
openstack flavor unset baremetal --property trait:CUSTOM_GOLD 2>&1|tee >
/dev/null
ironic node-update $BM_NAME add properties/memoy_mb="65536"
ironic node-update $BM_NAME add properties/cpu_arch="x86_64"
ironic node-update $BM_NAME add properties/local_gb="371"
ironic node-update $BM_NAME add properties/cpus="24"
ironic node-update $BM_NAME add
properties/capabilities="cpu_hugepages:true,cpu_txt:true,boot_option:local,
cpu_aes:true,cpu_vt:true,cpu_hugepages_1g:true"
node_uuid=$(ironic node-list | grep $BM_NAME |awk '{print $2}')
openstack baremetal port create $BF_MAC --node $node_uuid --local-link-connection
  hostname=$HOST_NAME --local-link-connection port_id="rep0=0" --
  physical-network datacentre --pxe-enabled true --is-smartnic
```
ironic node-set-provision-state $BM_NAME manage
ironic node-set-provision-state $BM_NAME provide

openstack quota set --class --instances 60 default
openstack quota set --class --cores 60 default

4.11 Boot Bare Metal Instance

To boot the bare metal instance, do the following:

openstack server create --flavor baremetal --image bm_centos --nic net-id=private r-bm-dcs81-bf
5 InfiniBand using TripleO

The following Mellanox network cards support the InfiniBand using TripleO and their firmware:

<table>
<thead>
<tr>
<th>NICs</th>
<th>Firmware version</th>
</tr>
</thead>
<tbody>
<tr>
<td>ConnectX®-6</td>
<td>20.26.1040</td>
</tr>
<tr>
<td>ConnectX®-5</td>
<td>16.24.1040</td>
</tr>
<tr>
<td>ConnectX®-4</td>
<td>12.26.1040</td>
</tr>
<tr>
<td>ConnectX®-3 Pro</td>
<td>2.4.5000</td>
</tr>
</tbody>
</table>

5.1 Installing and Running “NEO” and UFM”

To install and run InfiniBand fabric with OpenStack in the fabric, the following management software components are required: “UFM” and “NEO”.

1. Install and configure UFM.
   
   Please follow [this link](#) to acquire UFM.

2. Install and configure NEO.
   
   Please follow [this link](#) to install NEO.

3. Disable https from NEO, run the command below inside the NEO machine:

   ```bash
   $ yum install crudini
   $ crudini --set /opt/neo/controller/conf/controller.cfg API secure false
   ```

4. Configure NEO, to add UFM connection details.

   ```ini
   [UFM IB Params]
   #ip = ip,ip,...
   ip = <UFM server IP>
   #user = user,user,...
   user = <UFM user>
   #password = password,password,...
   password = <UFM password>
   #http or https
   supplier_protocol = https
   ```

5. Restart the NEO server.

   ```bash
   $ /opt/neo/neoservice restart
   ```

5.2 Configuring Undercloud

Starting from a fresh bare metal server, install and configure the Undercloud according to the official TripleO Master [installation documentation](#).

5.2.1 Preparing the Container Images

1. Clone the required packages.

   Create the “/home/stack/git” directory and clone into it the “networking-mlnx” package.

   ```bash
   $ mkdir /home/stack/git
   $ cd /home/stack/git
   $ git clone https://opendev.org/x/networking-mlnx.git
   ```
2. Create a Dockerfile to custom build the Nova compute image and install the required package.

```
$ git checkout stable/train -b stable/train

$ mkdir /home/stack/nova_custom
$ cat > /home/stack/nova_custom/Dockerfile <<EOF
USER root
RUN yum install python-networking-mlnx -x neutron -y
USER "nova"
EOF
```

3. Edit the “containers-prepare-parameter.yaml” file and add the following lines.

```yaml
parameter_defaults:
  DockerInsecureRegistryAddress:
    - 192.168.24.1:8787
  ContainerImagePrepare:
    - push_destination: "192.168.24.1:8787"
      set:
        tag: "current-tripleo-rdo"
        namespace: "docker.io/tripleomaster"
        name_prefix: "centos-binary-"
        name_suffix: ""
        ceph_namespace: "",
        ceph_image: "daemon"
        ceph_tag: "v4.0.0-stable-4.0-nautilus-centos-7-x86_64"
      excludes:
        - neutron-mlnx-agent
      push_destination: true
      includes:
        - nova-compute
        modify_role: tripleo-modify-image
        modify_append_tag: "-updated"
        modify_vars:
          tasks_from: modify_image.yml
          modify_dir_path: /home/stack/nova_custom
    - push_destination: true
      includes:
        - neutron-server
        - neutron-dhcp-agent
        - neutron-l3-agent
        modify_role: tripleo-modify-image
        modify_append_tag: "-updated"
        modify_vars:
          tasks_from: dev_install.yml
          python_dir:
            - /home/stack/gits/networking-mlnx
      push_destination: true
      includes:
        - neutron-mlnx-agent
        set:
          namespace: docker.io/mellanox
          tag: 1.0.0
```

Because kolla patch is not merged yet, we exclude the agent image from being pulled from the tripleomaster and include it in the repo “docker.io/mellanox”.
5.2.2 Updating the “neutron-ml2-mlnx-sdn.yaml” Environment File

Change the “neutron-ml2-mlnx-sdn.yaml” environment file to add the SDN information, and afterwards add it to the deployment command.

```bash
vi /home/stack/tripleo-heat-templates/environments/neutron-ml2-mlnx-sdn.yaml
```

Example:

```
# A Heat environment file which can be used to configure Mellanox SDN

resource_registry:
  OS::TripleO::Services::NeutronCorePlugin:
    OS::TripleO::Services::NeutronCorePluginMLNXSDN

parameter_defaults:
  MlnxSDNUsername: <user>
  MlnxSDNPassword: <password>
  MlnxSDNUrl: http://<IP>/neo
  MlnxSDNDomain: 'cloudx'
  NeutronCorePlugin: 'neutron.plugins.ml2.plugin.Ml2Plugin'
  NeutronMechanismDrivers: ['mlnx_sdn_assist','sriovnicswitch','openvswitch']
```

5.2.3 Adding the “neutron-mlnx-agent.yaml” Environment File to the Deployment Command

In the configuration below we set the physical network “datacentre” to be ethernet while creating new physical network “ibnet” to be InfiniBand.

In case of a mixed environment (Ethernet & InfiniBand) please use the following parameters:

```yaml
parameter_defaults:
  NeutronMechanismDrivers:
    ['mlnx_sdn_assist','mlnx_infiniband', 'openvswitch']
  NeutronBridgeMappings: 'datacentre:br-ex'
  NeutronNetworkVLANRanges: 'ibnet:350:360'
  NeutronPhysicalDevMappings: ['ibnet:ib0']
  BindNormalPortsPhysnet: ibnet
  MultiInterfaceDriverMappings:
    ['ibnet:ipoib,datacentre:openvswitch']
  NovaPCIPassthrough:
    - devname: "ib0"
      physical_network: ibnet
```

Example:

```bash
-e /home/stack/tripleo-heat-templates/environments/services/neutron-mlnx-agent.yaml
```
# A Heat environment that can be used to enable MLNX agent in neutron.

```yaml
resoure_registry:
  OS::TripleO::Services::NeutronMlnxAgent: ../../deployment/neutron/neutron-mlnx-agent-container-puppet.yaml
  OS::TripleO::Services::NeutronAgentsIBConfig: ../../deployment/neutron/neutron-agents-ib-config-container-puppet.yaml

parameter_defaults:
  ContainerNeutronMlnxImage: mellanox/centos-binary-neutron-mlnx-agent:1.0.0
  NeutronPhysicalDevMappings: ['datacentre:ib0']
  NovaSchedulerAvailableFilters: ['"nova.scheduler.filters.all_filters","nova.scheduler.filterspci_passthroughfilter"']
  MultiInterfaceEnabled: true
  BindNormalPortsPhysnet: 'datacentre'
  MultiInterfaceDriverMappings: ['datacentre:ipoib']
  IPoIBPhysicalInterface: 'ib0'
  NovaPCIPassthrough:
    - devname: "ib0"
      physical_network: datacentre
  ComputeSriovIBParameters:
    # Kernel arguments for ComputeSriov node
    KernelArgs: "intel_iommu=on iommu=pt"
    TunedProfileName: "throughput-performance"
```

Because [kolla patch](#) is not merged yet, notice the following line in the example above.

```yaml
parameter_defaults:
  ContainerNeutronMlnxImage: mellanox/centos-binary-neutron-mlnx-agent:1.0.0
```

## 5.2.4 Installing MLNX_OFED on the Overcloud Image on the Undercloud Machine

1. Download OFED installation package from [Mellanox site](#).
2. Install MLNX_OFED on the Overcloud image using the following script.

```bash
export LIBGUESTFS_BACKEND=direct
virt-copy-in -a overcloud-full.qcow2 MLNX_OFED_LINUX-4.7-1.0.0.1-rhel7.7-x86_64.tgz /tmp
evrt-customize -v -a overcloud-full.qcow2 --run-command 'yum install gtk2 atk cairo tcl gcc-gfortran tcsh tk -y'
vrt-customize -v -a overcloud-full.qcow2 --run-command 'cd /tmp && tar -xf MLNX_OFED_LINUX-4.7-1.0.0.1-rhel7.7-x86_64.tgz'
vrt-customize -v -a overcloud-full.qcow2 --run-command '/tmp/MLNX_OFED_LINUX-4.7-1.0.0.1-rhel7.7-x86_64/mlnxofedinstall --force'
```
3. Upload the modified image to the Undercloud.

```bash
$ openstack overcloud image upload --image-path <overcloud images folder> --update-existing
```
5.2.5 Generating the Required Roles

Generate the required roles [Controller, ComputeSriovIB] to use in the Overcloud deploy command

```
$ openstack overcloud roles generate -o roles_data.yaml Controller ComputeSriovIB
```

5.2.6 Update the “~/cloud-names.yaml” File

Update the “~/cloud-names.yaml” file to include following lines.

```
parameter_defaults:
  ComputeSriovIBCount: 1
  OvercloudComputeSriovIBFlavor: compute
```

5.2.7 Assigning the compute.yaml file to the ComputeSriovIB Role

1. Assign the compute.yaml file to the ComputeSriovIB role.
2. Update the “~/heat-templates/environments/net-single-nic-with-vlans.yaml” file by adding the following line.

```
OS::TripleO::ComputeSriovIB::Net::SoftwareConfig:
  /home/stack/nic_configs/compute.yaml
```

5.3 Deploying the InfiniBand Overcloud

Deploy Overcloud using the appropriate templates and yaml from heat templates as shown in the following example:

```
openstack overcloud deploy \
   --templates /home/stack/tripleo-heat-templates \
   --libvirt-type kvm \
   --r ~/roles_data.yaml \
   --timeout 180 \
   --validation-warnings=fatal \
   -e ~/cloud-names.yaml \
   -e /home/stack/containers-prepare-parameter.yaml \
   -e /home/stack/tripleo-heat-templates/environments/docker.yaml \
   -e /home/stack/tripleo-heat-templates/environments/network-isolation.yaml \
   -e /home/stack/tripleo-heat-templates/environments/net-single-nic-with-vlans.yaml \
   -e /home/stack/network-environment.yaml \
   -e /home/stack/nic_configs/network.yaml \
   -e /home/stack/overcloud-selinux-config.yaml \
   -e /home/stack/tripleo-heat-templates/environments/services/neutron-ovs.yaml \
   -e /home/stack/tripleo-heat-templates/environments/neutron-ml2-mlnx-sdn.yaml \
   -e /home/stack/tripleo-heat-templates/environments/services/neutron-mlnx-agent.yaml
```

5.4 Boot a Virtual Machine

On the Undercloud machine:

1. Load the Overcloudrc data.

```
$ source overcloudrc
```
2. Create a flavor.

```bash
$ openstack flavor create m1.small --id 3 --ram 2048 --disk 20 --vcpus 1
```

3. Create the guest image. Make sure that the guest image has MLNX_OFED installed on it.

```bash
$ openstack image create --public --file <image file> --disk-format qcow2 --container-format bare <image name>
```

4. Create the InfiniBand network.

```bash
$ openstack network create ibnet --provider-physical-network datacentre --provider-network-type vlan
$ openstack subnet create ibnet_subnet --dhcp --network ibnet --subnet-range 11.11.11.0/24
```

5. Create a direct port.

```bash
$ openstack port create direct1 --vnic-type=direct --network private
```

6. Boot a VM.

```bash
$ openstack server create --flavor m1.small --image mellanox --port direct1 vm1
```

### 5.5 Troubleshooting

<table>
<thead>
<tr>
<th>Issue</th>
<th>Cause</th>
<th>Solution</th>
</tr>
</thead>
<tbody>
<tr>
<td>Missing the InfiniBand interface inside the guest VM</td>
<td>Lack of the required InfiniBand kernel modules</td>
<td>Make sure that the required InfiniBand kernel modules (mlx5_ib, ib_core, ib_ipoib) are installed and loaded on the instance.</td>
</tr>
</tbody>
</table>

### 5.6 Limitations

- InfiniBand tenant network does not support IPv6
- Number of networks the user can create is 128 because of ConnectX family adapter cards firmware limitation

### 5.7 More Details

For more details please see the following wiki:

[https://wiki.openstack.org/wiki/Mellanox-Neutron-Train-InfiniBand](https://wiki.openstack.org/wiki/Mellanox-Neutron-Train-InfiniBand)
6 Configuring Mellanox SDN Mechanism Driver Plugin Using TripleO

6.1 Configure and Prepare the NEO

Use the links below, to execute the necessary preliminary steps to prepare the NEO machine:

1. NEO introduction/installation.
2. Configure NTP on NEO machine.

```
ssh root@<NEO_IP> ntpdate 0.asia.pool.ntp.org
```

6.2 Enable LLDP on Mellanox Switch

Enable LLDP on the Mellanox switch:

1. Login as admin.
2. Enter config mode.

```
switch > enable
switch # configure terminal
```

3. Enable LLDP globally on the switch.

```
switch (config) # lldp
```

6.3 Install RPM Package on Container Image

Before deploying the overcloud, create /home/stack/containers-prepare-parameter.yaml in order to modify the container image with required package python-networking-mlnx.

1. Download the package rpm file python2-networking-mlnx from this repo.
2. Move the package to /home/stack/rpm_path/ folder.
3. Generate /home/stack/containers-prepare-parameter.yaml, if it does not yet exist, using this command:

```
(undercloud) [stack@undercloud ~]$ openstack tripleo container image prepare
   default --local-push-destination
   --output-env-file /home/stack/containers-prepare-parameter.yaml
```

4. Modify the /home/stack/containers-prepare-parameter.yaml file to install the package on the container image.

Example:

```
parameter_defaults:
DockerInsecureRegistryAddress: - 192.168.24.1:8787
ContainerImagePrepare:
  - push_destination: true
    set:
      tag: "current-tripleo-rdo"
      namespace: "docker.io/tripleostein"
      name_prefix: "centos-binary-
      name_suffix: ""
```
neutron_driver: null

- push_destination: true
  includes:
  - neutron-server
  modify_role: tripleo-modify-image
  modify_append_tag: "-updated"
  modify_vars:
    tasks_from: rpm_install.yml
    rpms_path: /home/stack/rpm_path/

Add the file `/home/stack/ containers-prepare-parameter.yaml` to the deploy command using `-e` parameter and deploy the overcloud.

### 6.4 Configure the Mellanox SDN Mechanism Driver Plugin

Modify the file `/usr/share/openstack-tripleo-heat-templates/environments/neutron-ml2-mlnx-sdn.yaml` in the following way:

```yaml
# A Heat environment file which can be used to configure Mellanox SDN
resource_registry:
  OS::TripleO::Services::NeutronCorePlugin:
  OS::TripleO::Services::NeutronCorePluginMLNXSDN
parameter_defaults:
  MlnxSDNUsername: '<sdn_username>'
  MlnxSDNPassword: '<sdn_password>'
  MlnxSDNUrl: '<sdn_url>'
  MlnxSDNDomain: 'cloudx'
  NeutronCorePlugin: 'neutron.plugins.ml2.plugin.Ml2Plugin'
  NeutronMechanismDrivers: ['mlnx_sdn_assist', 'sriovnicswitch', 'openvswitch']
```

The domain name 'cloudx' and the SDN credentials need to be changed as required.

Add the file `/usr/share/openstack-tripleo-heat-templates/environments/neutron-ml2-mlnx-sdn.yaml` to the deploy command using `-e` parameter and deploy the overcloud.
6.5 Set NTP Server

It is important that the time on the overcloud and NEO machine are synchronized.

In parameter defaults section, add the following line to set NTP server:

```
parameter_defaults:
  NtpServer: ['0.asia.pool.ntp.org', '1.asia.pool.ntp.org']
```

NEO machine and overcloud nodes must have the same NTP servers.

6.6 Install LLDPAD Package to Overcloud Image

LLDPAD package must be installed on all overcloud nodes by installing the package on the overcloud image before deploying:

```
virt-customize -v -a overcloud-full.qcow2 --run-command \
  "sudo subscription-manager register --username <USERNAME> \
  --password <PASSWORD> --auto-attach ; yum install lldpad -y ;\n  sudo subscription-manager unregister"
```

6.7 Configure LLDPAD in First Boot

a. Create file first_boot.yaml that contains the following content:

```
heat_template_version: rocky

description: >
  Start and configure LLDPAD

resources:
  userdata:
    type: OS::Heat::MultipartMime
    properties:
      parts:
        - config: {get_resource: configure_lldp}

configure_lldp:
  type: OS::Heat::SoftwareConfig
  properties:
    config: |
      #!/bin/bash
      set -eux
      set -o pipefail
      hostnamectl set-hostname $(hostname -s).localdomain
      hostnamectl set-hostname --transient $(hostname -s)
      sudo systemctl enable lldpad
      sudo systemctl start lldpad
      interface=p6p1
      lldptool set-lldp -i $interface adminStatus=rxtx
      lldptool -T -i $interface -V sysName enableTx=yes
      lldptool -T -i $interface -V portDesc enableTx=yes
      lldptool -T -i $interface -V sysDesc enableTx=yes
      lldptool -T -i $interface -V sysCap enableTx=yes
      lldptool -T -i $interface -V mngAddr enableTx=yes
      lldptool set-tlv -i $interface -V mngAddr ipv4=$(ip a sh br-ex | grep " inet " | head -1 | awk '{print $2}' | cut -d'|' -f1);```
b. In your `network-environment.yaml` add the following line:

```yaml
resource_registry:
  OS::TripleO::ComputeSriov::NodeUserData: ./first_boot.yaml
```
